Over the years, research has shown that groups working on complex multifaceted questions and issues benefited by having intellectual and cultural diversity (Adler, 2002; Mazur and Biatostocka, 2010; Page, 2007). According to Kincheloe and Steinberg (2008), "The more we understand about the world, the more complex it appears to be ... In this sense, different frames of reference produce multiple interpretations and multiple realities" (p. 138). As issues increase in both size and complexity, so does the need for diverse culturally intellectual frames of reference for identifying solutions to problems. Diverse frames of reference allow individuals to see issues through multiple perspectives, increasing their ability to come up with more complete and encompassing answers. In describing the importance of multiple, diverse perspectives, Kincheloe and Steinberg (2008) state, "In a sense, the single photograph of Cartesian thinking is replaced by the multiple angles of the holographic photograph" (p. 139). Diversity within sciences is likely to be as important as environmental and species diversity is to ecosystems.

Indigenous Knowledge Systems

Through generations of careful observation and hands-on scientific management, Indigenous peoples have and continue to impact local environments. Indigenous peoples of the United States understood and maintained their environmental knowledge according to the specific environments where they lived. In this way, IKS are as diverse as the environments and people who have developed them.

Indigenous peoples around the world have been deeply rooted in their homelands for thousands of years. Over time Indigenous peoples have created their own ontological understandings and knowledge bases, explaining their homelands and worldviews through oral traditions passed down from generation to generation (Barnhardt and Kawagley, 2005; Berkes, 1999; Cajete, 2000; Happynook, 2004; Lake, 2007; Rigney, 2001). Barnhardt and Kawagley (2005) explain, "The Depth of Indigenous knowledge rooted in the long inhabitation of a particular place offers lessons that can benefit everyone, from the educator to scientist, as we search for a more satisfying and sustainable way to live on this planet" (p. 9). Research suggests that integrating IKS alongside Western science practices is essential for maintaining global cultural diversity and the biological diversity connected to traditional management systems (Bohensky and Maru, 2011). Western scientific researchers are discovering and are growing more accepting with combining these two unique systems of knowledge that were once thought to be incompatible. For example, Bohensky and Maru (2011) state, "Co-management arrangements that allow knowledge to be integrated through collaboration can build social as well as ecological resilience" (p. 2). Integrating IKS with Western science can lead to more complete answers, because the solutions come from a variety of perspectives and also serve a greater range of invested stakeholders. Within the past 15 years there has been some progress made through participatory action research (PAR) projects that seek to include community knowledge into on-the-ground environmental research and educational projects. However, looking at a historical level the process of making change through collaborative efforts has been a very slow process.

Western science knowledge systems

Western science can and has included as diverse a set of definitions as Indigenous knowledge, incorporating everything within the natural world including social and cultural understandings. Western science information has been obtained primarily through the isolation of individual components. Webster's New Collegiate online dictionary defines science as knowledge attained through study or practice, covering truths about nature's general laws and has been tested through the scientific method. Since its conception western science has become the dominating perspective excluding many other ways of knowing as untruthful. The notion that all science knowledge needs to be tested through the scientific method has allowed western science to dominate science understandings. As western science increased in power it has also continued to narrow what can be categorized as scientific knowledge to only include information that is testable, repeatable, observable, and falsifiable (Shuttleworth, 2009). These same perspectives of western science knowledge systems being superior and allowing for the elimination of all other ways of knowing is the same notion that European colonizers utilized as a means to try to remove Indigenous peoples North America.

Western settler colonialism

Settler colonialism is a form of colonialism in which the colonizers come to stay. As noted by Tuck and Yang (2012) "settler colonialism is different from other forms of colonialism, in that the settlers come with the intention of making a new home on the land, a homemaking that insists on settler sovereignty over all things in their new domain" (p. 6). By design settler knowledge becomes the dominant form of knowledge, replacing all other forms of knowledge, including Indigenous Knowledge Systems.

Impact of diseases

While settler colonial intent and actions of destruction upon Indigenous peoples was by no means an accident (Tuck and Yang, 2012) it is important to understand how diseases at the point of impact affected most Indigenous peoples and their knowledge systems. Utilizing North America as an example one will learn that as population numbers of Europeans increased in America, so did the number of European-born pathogens (Carlos and Lewis, 2012). Diseases devastated many Native American populations causing loss of life and cultural knowledge, including land management practices. European diseases were the first devastating and immediate impacts on Indigenous peoples and their environmental management (White and Cronon, 1988).

Indigenous population counts and deaths associated with disease are debatable. Indigenous populations at the time of contact to the United States have been estimated at numbers as low as one million and as high as 18 million and every number in between (Carlos and Lewis, 2012). However, by the early 20th century Indigenous populations in the US and Canada have been reported at around 500,000 (Ubelaker, 1988). In general, tribes least affected lost up to 50% of their populations while others suffered much more devastating effects. Communities held a considerable amount of intellectual knowledge understood by all. In addition, there was family knowledge held within families. As diseases spread through communities it killed entire families and often communities. Consequently, unique knowledge held within each family was lost.

Some of the most unfathomable acts of settler colonialists involved utilizing many of the initial diseases that had already been proven to be destructive. It has been proven that settler colonialists' purposefully utilized smallpox blankets as a means to kill off Indigenous populations. According to Valencia-Weber (2003),

Smallpox blankets infected American Indians as the result of intentional acts where the donor (Euro-American colonial settlers) knew of the deadly microbes ... the concern here is for the intentional in the relationships mandated when Euro-Americans encountered the Natives and had to deal with mutual, as well as conflicting interests (p. 406).

Maliciously conceived settler colonialist's acts such as the use of germ warfare to remove Indigenous peoples from their homelands illustrate settler colonialist intentions to do anything possible to take over the Americas.

Settler greed

As settler populations continued to increase so too does their greed and desire for land and resources. Increased want for land within what is now the US came at the cost of the Indigenous peoples who continued to be removed, relocated, and decimated (Pevar, 2012). Policies such as the 1830 Indian Removal Act and the 1887 Dawes Act supplied additional lands through the removal of many Indigenous peoples from their traditional homelands (Pevar, 2012). In 1830 President Andrew Jackson put the Indian Removal Act into effect. President Jackson believed that Native Americans were a threat to American settlers and society and needed to be removed in order for American settlers to take their place in the newly forming United States (Bradey, 2011). In 1838 over 17,000 Cherokee men, women, and children in the Carolinas, Georgia, and Tennessee were forcefully taken and placed in stockades to await removal to Oklahoma country (Mooney, 1992). Provided with 645 wagons, the removal of the more than 13,000 remaining Cherokee people began in October 1838 and ended in March 1839. It is estimated by Mooney (1992) that more than 4000 Cherokee died as a direct result of removal. Acts like the one described above were not limited to only the Cherokee tribe. It is estimated that over 15,000 Indigenous peoples died on the Trail of Tears (Pevar, 2012).

In 1887 the US passed the General Allotment Act, also known as the Dawes Act (Pevar, 1992). Pevar (1992) describes the purpose of the Dawes Act, "... to break up tribal governments, abolish Indian reservations, and force Indians to assimilate into white society" (p. 5). The Dawes Act changed ownership from communal lands to individualized parcels with specific settler colonial management rules and regulations associated with each piece of land. If Indigenous peoples did not comply with regulations their parcels of land were subject to be taken and given or sold to European settlers, who understood how to fulfill regulations. Of the 140 million acres owned by Indigenous peoples in 1887, only 50 million acres remained under Indigenous ownership by the end of the Allotment Act period in 1934 (Pevar, 1992).

Shifting land management

With Indigenous removal by settler diseases and settler land policies came a shift in land management practices based upon settler colonialist philosophies of scientific management. Settler land philosophies were based upon the understanding of having dominion over the land and its resources. In addition, successful management was measured through one's ability to produce excess goods (Tuck and Yang, 2012). By design, settler colonizing science systems have been constructed to show that all other ways of knowing outside of the colonizers are inferior and therefore irrational (Rigney, 2001). As a means to colonize, Indigenous peoples were not allowed to maintain or practice their social systems, knowledge, traditional, and cultural sciences. Consequently, colonial settler-based science knowledge systems have designed an Indigenous reality through their own scientific discussions with no Indigenous input (Foley, 2003). When Indigenous Knowledge and peoples are left out of scientific discussions and education society as a whole loses out.

Exclusion of indigenous land management

Since the arrival of Euro-American colonizers to the United States, the Indigenous model of culture and science-based knowledge systems has been researched, described, and disseminated through a strictly Western-based lens (see Bohensky and Maru, 2011; Rigney, 2001). By design, the Western model forcefully removed perspectives that did not follow Western methodologies. This scientific model is described best through the title of Colin Scott's (1996) article "Science for the west, myth for the rest." In many cases exclusion of Indigenous knowledge systems has led to management and policy issues that affect not only Indigenous peoples but also the environments that sustain all peoples.

Protection versus sustainable resource utilization

Although many Indigenous peoples have maintained and expanded their knowledge systems and connections to the environment, Western laws and policies have often times overruled Indigenous knowledge and practices (Blackburn and Anderson, 1993). Western policies, in the form of national parks and federally protected environments, aim to protect environments, species, and lands. However, to ensure protection, these policies often prevent humans from interacting with those environments. Human removal goes directly against Indigenous cultural teachings, values, and responsibilities. As integrated members of the natural world Indigenous communities continue to shape environments through sustainable cultural management practices (Happybrook, 2004; Martinez et al., 2008). Therefore, policies and laws that exclude Indigenous cultural obligations and knowledge systems lead Native Americans to either be criminals in the Western sense or to assimilate and cease their cultural practices completely. This leads to devastating results for both the Indigenous communities as well as their environments. The concept of protection versus sustainable utilization remains an issue between Indigenous and Western land managers. One way to solve these conflicts is through educational discussions and on-the-ground participatory action research (PAR) projects that aim to manage and teach through the collective interested parties. In addition, there is a need for bi-cultural education programs in the natural resource and other sciences that can teach future resource managers about the foundational values found within Indigenous and Western worldviews (Lipe, 2013).

It is through the understanding of these two unique systems that a dialogue can start to take place on how and where IKS and Western science can be used to work together. Bi-cultural education programs can help future Indigenous and non-Indigenous scientists to learn how to communicate and work within Indigenous and Western science worlds. Bi-cultural education programs can also be used to help bridge Indigenous and western science worlds and create avenues for cross-cultural educational and on the ground land management partnerships. As discussed earlier collaborative cross-cultural education efforts create more comprehensive and encompassing natural resource management decisions by teaching individuals to see the world through diverse frames of reference. One example illustrating the need for diverse frames of reference is fire management within the United States.

Different perspectives for fire management

One Western policy example that has greatly impacted the Indigenous peoples and environments around the world, especially within the Pacific Northwest of the US, is the Weeks Act of 1911, also known as “fire suppression.” Fire, in its natural form, has transformed large portions of land throughout The United States and the world (Boyd, 1999). “Euro-American civilization, challenged by this uncontrollable force of nature, had a cultural aversion to fire. Since 1900 we (Euro-Americans) have tried to eliminate most forest fires with varying success. But, in just one century, settlement has changed the landscape, altering biodiversity, forest growth, wildlife habitat, and a host of other factors” (Barrett and Arno, 1999, p. 62). When the Indigenous peoples’ understanding, knowledge, and on-the-ground management were removed from their homelands of the Pacific Northwest and beyond, there were immediate repercussions to the environments they managed. For example, Ross (1999) states,

It has been documented that Native Americans were cognizant of benefits derived from selective burning. In contrast, most of the areas Euro-American settlers’ interpretation and policies suggest that they did not understand the ecological benefits of prescribed burning. By opposing Indian prescribed burning, Euro-Americans created an environmental situation that actually encouraged the heavy accumulation of dead vegetation, windfall, and deadfall; as well as change in certain species types, seed propagation, and alteration of fire resistance of some plants; increasing disease caused by bacteria, fungi, parasitic plants and viruses (p. 277).

Today society is dealing with the forest issues caused by the shift of management regimes from that of Indigenous peoples into the hands of Western policymakers.

Western fire suppression policies. The Weeks Act of 1911 was established as a land protection policy that included fire suppression of natural as well as human caused fires from the United States landscape (Otoole, 2007). Fire suppression policies and laws were made with no concern for Native American tribes and their knowledge systems. Fire suppression has created catastrophic changes in many forest ecosystems across the country (Stephens et al., 2007). The US government gave the Forest Service the right to suppress fires at any cost (Otoole, 2007). Since the establishment of the Weeks Act, fuel loads have increased in most US forests to a state of emergency. Helms (1998) identified fuel loads as the amount of combustible fuels that include ladder fuels identified as vegetation that provides vertical continuum between vegetation strata and can allow fires to reach crowns of trees. Increased fuel loads allow fires to grow to catastrophic crown levels. Crown level fires lead to the destruction of entire forest systems (Jain et al., 2012). With the removal of both natural and anthropogenic (man-made) fires by the Weeks Act, there has been a shift in fire regimes causing the very conditions that Indigenous peoples avoided through controlled burns.

Indigenous knowledge and burning practices. Indigenous peoples understood that fire, in its natural form, cannot be controlled or eliminated in ecosystems. Barrett and Arno (1999) state, “After a millennia of subsistence in the Northern Rockies, Indians were well accustomed to interacting with fire in the environment” (p. 62). Through careful observations and experimentation over multiple generations, Indigenous peoples within the Pacific Northwest gained the knowledge to respect and work with fire both in its natural and anthropogenic forms as a management tool. As noted by Turner (1999), “Controlled landscape burning required a detailed, in-depth knowledge of natural systems, especially ecological characteristics of vegetation and the successional nature of plant communities, as well as of various geographical and climate features of the landscape” (p. 201). For example, Native Americans demonstrated their in-depth knowledge by burning in a variety of areas during the late summer and early fall, coinciding with the natural fire regime (Blackburn and Anderson, 1993; Boyd, 1999). Furthermore, in observing how natural fires affected plant succession, fire was used as a tool to maintain desirable early successional stages with easily accessible nutrients (Boyd, 1999). Through time and use of fire the Indigenous peoples of the United States built a relationship with fire in order to maintain biodiversity and the health of their populations.

Indigenous fire and environmental management

In addition to establishing a relationship with fire for the benefit of humans, Indigenous peoples also used fire to enhance and manage ecosystems. Boyd (1999) describes Indigenous use of controlled burns in the form of spot fires. First, spot fires were used to reduce the fuel loads, decreasing chances of catastrophic crown fires. If a crown fire broke out, an entire ecosystem could be at high risk of being eliminated. Second, after a spot fire, new, highly-nutritious growth emerged that was utilized by animal species in the area. Third, spot fires were used to keep oak savannas open in order to make acorns more accessible to both animals and humans. Therefore, Indigenous peoples were able to establish a complex relationship between the environment, fire, and themselves. It is important to understand that while the Indigenous peoples of the United States utilized fire at different environmental

spatial and temporal scales. In this way, not all Indigenous peoples of the United States utilized fire to the same degree. The next several paragraphs provide specific ways Indigenous peoples of the Pacific Northwest utilized fire as land management tool in fishing, crop and range management, and for creating basketry materials.

Connecting fire to fisheries. With six different species of salmon returning to different river systems at different times throughout the Pacific Northwest, salmon is a main staple of food for many Indigenous peoples of the Pacific Northwest. Salmon returns for river systems like the Columbia River watershed were capable of having runs of 13–16 million fish annually (Taylor, 1999). Indigenous peoples are found from the mouth of the Columbia River along the Oregon/Washington Coast to the headwaters and tributaries that cover a span of over 260,000 square miles and seven states (“Columbia River,” 2012). A few reasons fire was used in fishing was to increase water levels, create salmon harvesting materials, baskets for salmon storage and trade materials, and for cooking salmon.

Fire was also used for creating materials utilized for making fishing nets and other fishing materials. Different techniques of fishing are utilized to capture salmon depending upon river conditions and where along the Columbia River continuum peoples live (Taylor, 1999). Different ways of storing food for wintertime and for trading was also very important. Most tribes along the Columbia River system dried salmon and pounded it into pemmican as a way to store the highly nutritious food in smaller packable sizes for winter storage and for trading (Taylor, 1999). Pemmican was stored in large baskets that were often traded for goods not found within the area. There was no place larger or better known to Native Americans of the Pacific Northwest for fishing and trading networks than Celilo Falls, found at the Dalles in Oregon (Taylor, 1999). Burning for materials varied depending upon the environment and the plant species found there. The fishing techniques most utilized by Indigenous peoples included but were not limited to spears, dipnets, poisons, seines, gillnets, traps, baskets, and weirs (Taylor, 1999). Each fishing technique and apparatus used required quality materials that came from maintained environments that produced the required resources. Most of the plant materials used in netting were from local areas and included iris, cedar bark, and silk grass. Through trading of harvested salmon, some tribes were able to obtain Indian hemp and bear grass from tribes found on the plateau (Taylor, 1999). Creating fishing and food storage materials required management of local environments. Management techniques and scale varied depending upon how much and what kinds of materials were needed.

Most tribes burned areas as a means to produce high quality materials for making cordage, netting, baskets, clothing, tools, and ceremonial items (Blackburn and Anderson, 1993). One such item was seine nets. Seine nets on the Columbia River have been reported as being up to 600 feet long and 16 feet tall (Taylor, 1999). According to Blackburn and Anderson (1993), “Craig Bates of the Yosemite Museum has estimated that approximately five stalks of Indian hemp or milkweed would have been required to manufacture one foot of cordage” (p. 23). Therefore, it would take a colossal number of high-quality materials to build and maintain a net the length of two football fields. Fire was the tool used to produce the majority of the quality materials used in making these goods. In addition, in many places in California, fire was used to burn large areas creating smoke filled environments at different times of the year. Heavy smoke areas from fire could have caused a change in lowering water temperature (Lake, forthcoming). Research in the Northern California area is being conducted to determine what effect dense smoke conditions may have had on rivers with salmon runs on them. Smoky covered environments in areas with heavy fire use such as northern California may have caused a decrease in water temperatures helping salmon species during late fall spawning times.

In addition, fire was utilized in fishing to increase water availability and levels. Burning areas with vegetation decreased water evapotranspiration rates, which increases underground water and replenishes aquifers (Lake, 2007). Replenished aquifers in turn increase the water flows and availability of water in salmon-producing rivers and tributaries. Depending upon species and area burned, fire could make significant increases in water availability, especially in later fall.

Enhancing crop production through burning. As a high context knowledge system incorporating multiple environmental variables and factors, Indigenous fire management practices were used at different temporal scales for multiple purposes. According to Boyd (1999), “Willamette Valley Indians must have had some understanding of the long-range affects that periodic firing had on brush and refuse to make acorn gathering easier, reduce competition from other plants, kill parasites, and encourage a higher level of acorn production” (p. 120). In some areas fire was used to facilitate growth of medicines (Lake, 2007). Keeping areas open was another primary reason used to increase crop yields while decreasing unwanted encroaching species (Lake, 2007). Burning also maintained and controlled pest species such as acorn weevils that could infest crops if not taken care of. Furthermore, Schenk and Gifford (1952) note, “Karuk women, for example, reported that the trees are better if they are scorched by fire each year. This kills disease and pests” (p. 382). Therefore, fire was used to manage crops by reducing weeds, killing parasites, and eliminating other encroaching species.

Fire and range management to increase ungulate populations. According to Boyd (1999), in certain areas fire was used “to maintain open, park-like conditions, which were conducive to ungulate species, fire removal of windfall and deadfall and understory fire management was necessary” (p. 279). Depending upon seasonality, many areas were burned as a means to both increase range and forage availability for deer and elk species in higher elevations, nearer to winter. Boyd continues, “Firing areas to shoot deer more easily resulted in increased browse and pasturage for larger numbers of deer and elk” (p. 120). Other areas were burned as a means to reduce palatable vegetation for ungulate species, forcing animals to move lower into valley hunting areas. Ross (1999) describes, “Burning destroyed tree moss which the deer feed on in winter season, and by burning the moss, the deer are obliged to descend into the valleys for food, making them more available for Indian predation” (p. 281). Other areas were burned as a means to drive ungulate species, primarily deer, into snares or hunting parties. Native American burning was not just for short term hunting goals, however. LaLande and Pullen (1999) point out, “Fire had longer-term wildlife goals as well; goals that might be years in the future ... Indians in South Western Oregon employed fire to improve and maintain wildlife habitat” (p. 261).

Fire environments and basket weavers' expertise. For most Indigenous groups, baskets and basket materials were among the most important and heavily utilized tools in everyday life. Controlled burning by Indigenous basket weavers has been utilized for centuries as a means to enhance the growth of certain basket materials (Ortiz, 1993). Basket weavers are plant biologists, botanists, and environmental managers all rolled into one. Weavers understand how plants work and how to create optimal conditions for growing materials best suited for making the best baskets. Basket weavers burn for a host of reasons. In describing the benefits of burning, "It [fire] returns important nutrients to the soil, eliminates unhealthy plants, reduces pests, and keeps understory vegetation sufficiently spaced, assuring that each plant will get the optimum light, water, and nutrients" (Ortiz, 1993, p. 204). Oftentimes basket material tracts of land are managed in much the same way as a garden. According to Ortiz (1993), "Basket weavers utilize the same horticultural methods used by gardeners in their yards: judicious harvesting, pruning, cultivation, and debris clearing. They also utilize controlled burning" (p. 199). Due to the changes in land management policies and practices many of these garden-like environments have been or are in jeopardy of being lost.

The example of fire illustrates how different cultures can bring different experiences and values to environmental land management discussions. In this case, one group views fire as damaging to the health of the ecosystem, therefore wanting to control and eliminate it, while another group views fire as a tool to maintain the health of ecosystems. However, because the US government and Western scientists have control over fire policies, the results have allowed for increased fuel loads and damages caused by increased crown fires. The wildfire crisis in the United States is a direct result of a longstanding land management policy failure (Busenberg, 2004). This crisis may have been avoided had the Indigenous peoples of the United States and their knowledge base been part of the educational and land management decision making processes since the arrival of colonizing settlers. Therefore, the scientific community needs to continue to expand their understandings of science in order to allow diverse perspectives to be heard and utilized.

Native American land management today

Through treaties that created Government-to-Government relationships between the US and Native American tribes, the US Government has a legal obligation to work with Indigenous tribes on land management issues (Pevar, 1992, 2012). Indigenous peoples of the United States own and manage millions of acres of both privately owned and US governmental ceded lands "that are entrusted to the US government. Trust lands are lands in collective tribal holding for which the secretary of the Interior has a continuing trust responsibility to manage in a manner to benefit the respective tribe" ("Appendix B," n.d., p. B-2). Tribal organizations maintain over 15,990,000 acres of forestlands, including more than 5,700,000 acres of commercial forestland and 8,700,000 acres of woodlands ("National Indian Forest," 2012). Found alongside these nearly six million acres of forestlands belonging to Indigenous peoples are over 2500 shared miles of common border and long-term stewardship responsibilities for the forests entrusted to their care ("Proposal for the Tribal Forest", 2011).

In many cases tribes continue to manage lands through both traditional and modern technology. While tribes do understand the economic value of timber, they also see the forest as much more than just trees and economic wealth. As mentioned by Wells (as cited in Simmons, 2012), in an interview with Chief Tanner of the Coquille tribe,

We get many things from the forest—canoes, baskets, clothes, shelter, fir, cedar, spruce, bear grass, camas, and we use all of these things, but they also have a spiritual value which we honor as our ancestors. What we take, we try to give back; what we don't need, we try not to take (p. 2).

In this way, tribes offer valuable insights and ethical standards that are useful to current land management practices. According to Prober et al. (2011),

There has been increasing global interest in accounting for different knowledge frameworks in the sustainable management of natural resources ... it is assumed that this will result in more resilient social-ecological systems through the incorporation of a broader information base, consideration of a wider diversity of culturally derived ideals, and elucidation of conflicts and synergies (p. 1).

In order to work together more effort needs to be made to create avenues for cross-cultural education between Indigenous and Western science.

Educating through diversity for the Future? Increasing the ability and number of individuals who can transit between Indigenous and Western ways of knowing and interacting with natural resources can prove beneficial for all. Collaborative involvement of tribes and tribal partners working with the Forest Service is essential to what the Department of Agriculture calls the "All Lands, All Hands" approach to managing ecosystems (National Association of Foresters, 2010). Creating a new land management regime through natural resource education curricula based upon sustainability in which all stakeholders work together can improve forest health, promote collaborative relationships, and increase landscape-scale management objectives and health of environments for all people.

While much of this paper focuses upon the United States, it is essential that we begin to identify and work with all Indigenous peoples around the world. It was recently reported that while Indigenous peoples around the world only control 20% of the lands surface they hold 80% of its diversity (<https://doi.org/10.4060/cb5131en>). The knowledge, understandings and knowhow can be found in and with Indigenous knowledge and the people places and relationships they hold to their local places. It is also through these same relationships that the earth herself can be healed. However, we must incorporate Indigenous peoples and their knowledge systems to help us understand how to create these relationships and help provide foundational understandings for how to move and be in place. It is through these understandings and connections that we be shown how to care for our earth. In a recent report by the Indigenous peoples currently only hold 20% of the earth's land but maintain over 80% of the world's diversity (<https://doi.org/10.4060/cb5131en>). This is by no means a coincident.

It is essential that we find a way to bring diverse perspectives of knowing and understanding together to be taught side by side. Natural resource education and curricula that includes cultural diverse perspectives is one way to provide future land managers and policy makers with the tools required for making better and more encompassing land management decisions. Bi-cultural education programs that teach the foundational values of both Western and Indigenous sciences can be helpful for teaching students from different cultural backgrounds about the similarities and differences between Western and Indigenous scientific perspectives (Lipe, 2013). In turn, these understandings can be beneficial for establishing a baseline point for dialogue used in bridging the gap between these two unique scientific perspectives. Whether policymaking or on-the-ground management, we as a larger society can no longer rely on Western science to come up with all the answers. Indigenous peoples and knowledge systems must be included into environmental education and management strategies if we are going to have any chance of a sustainable future.

Shifting paradigms of science education through Indigenous Knowledge courses and programmatic changes. The Sustainable Community Food Systems (SCFS) Bachelors of Applied Science Degree program at the University of Hawaii West Oahu, is a multidisciplinary experiential-based program that teaches the next generation of foods systems professionals the skills required in solving real world problems. In 2017, the SCFS program began developing a line of Indigenous Knowledge courses as a means to diversify its course offerings. These courses utilized both Indigenous and western science-based knowledge in order to expand students' knowledge bases and provide students with exposure into how western and Indigenous scientific based knowledge system can work together to provide answers to some of issues facing the state of Hawaii and beyond. The following is a list of courses that were developed along with a short description of what each course covered.

- **SCFS 315-Wild Game Management-** This 3-unit field course that provides an analysis of sustainable wild game management and processing techniques from both western science and Indigenous Knowledge perspectives. Through assigned readings, guest presentations from practitioners, and real-life first-hand experiences, this course seeks to teach the importance of wild game and food management as it relates to ecological sustainability and food production. This course describes Indigenous relationships and responsibilities involved in sustainable bio-cultural utilization of wild game management. It will also demonstrate how managing wild game can be another relevant component to helping fix today's global issues of natural resource management and food security.
- **SCFS 370-Ahupua'a Perspectives-** This course focuses on Hawaiian Natural Resource Management. It will provide an in-depth understanding of Hawaiian natural resource management through the study of connections found from mountain top to sea. Exploring historic as well as current documentation and case studies students will learn natural resource perspectives of Hawaiians pre-European contact. In addition, students will learn how Hawaiian based environmental management practices are still alive today and can provide valuable insights as we as a greater society look to living more sustainably.
- **SCFS 385-Fishponds and Near Shore Fisheries-** This course focuses on Hawaiian fisheries management past present and future. Centered around readings, case studies, guest presenters and field trips students will learn about Hawaiian based understandings of historical fisheries management. Included in this course will be in depth discussions about how and why Hawaiians designed, built and managed fishponds before Euro-American contact. In addition, the course will focus on teaching how many of these cultural practices are still relevant today. This course provides experiential based site visits to current fishponds that are being restored as a means to be a part of and learn current strategies for rebuilding and restoring Hawaiian fishpond for a more sustainable future.
- **SCFS 415-Mahi ai kalo-** This course provides and in depth understanding of Hawaiian lo'i agricultural practices both before and after Euro American contact. Through readings, guest presenters, and field trips students will learn and experience first-hand the intricacies within Hawaiian cultural and scientific understandings within lo'i kalo. In addition, this course will examine how these understandings are as relevant today and, in the future, as they were in the past.
- **SCFS 455-Ethics in Worldviews-** This course provides an in-depth understanding of how worldview shapes education, on the ground management, and policies of natural resource management. Students will learn about Native American, Hawaiian, and Western European based environmental world and how these beliefs that are shaped by the foundational values and ethics within them affect natural resource management. In addition, students will learn about how understanding diverse perspectives can help provide more encompassing answers to the complex multilevel environmental issues we are facing today, leading to a more sustainable future.
- **SCFS 485-Traditional Ecological Knowledge (TEK)-** provides an introduction to understanding of how Traditional Ecological Knowledge (TEK) can shape education, on the ground management, and policies of natural resource management. Students will learn about Native American, Hawaiian, and Western European based environmental knowledge and how these beliefs that are shaped by the foundational values affect natural resource management. In addition, students will learn about how

understanding diverse perspectives can help provide more encompassing answers to the complex multilevel environmental issues we are facing today, leading to a more sustainable future.

Including Indigenous courses as degree requirements—While the SCFS staff believed these courses were a valuable addition to the program they quickly realized that as electives it was not enough. So, in 2021, the program staff wrote a United States Department of Agriculture grant called, The Undergraduate Pathways Bridging Excellence in Agriculture and Tradition (UPBEAT), its main focus is to help Indigenize the Sustainable Community Food Systems Bachelors of Applied Science (SCFS-BAS) undergraduate degree program at the University of Hawaii West Oahu. The UP-BEAT project seeks to expand the systematic integration of Indigenous Knowledge and community-based experiential learning. One aspect of this grant was to make programmatic changes to include the courses listed above as graduating requirements instead of elective courses. By making these courses requirements both current and future SCFS students will take both Indigenous and western science-based courses in order to graduate. These courses will provide a detailed perspective along with hands on practical skills and tools required to utilize both Indigenous and Western science knowledge systems to solve food systems challenges of Hawaii and beyond. The SCFS program is using these experiential based courses to reconnect students to their local environments. In the end the program believes that by connecting Indigenous and western science knowledge it will provide the essential skills required to transition current food systems into a more equitable and sustainable system for all.

Ohneganos Ohnegahde:gyo

From the perspective of the traditional Haudenosaunee, we speak in terms of responsibilities with respect to water, not in terms of water rights. From time immemorial, we have held the view that the "law of the land" is not man-made law, but a greater natural law, the Great Law of Peacethe root words for "rain" in Mohawk means expensive, or precious or holy. Culturally, we would not abuse this resource.

King (2007, p. 452).

Indigenous communities in Canada are experiencing severe water and health crises caused by climate change and colonialism, but are also uniquely positioned to contribute to the solutions to these problems by accessing Indigenous Knowledge (IK). IK pedagogy acknowledges diverse ways of knowing and respects the pluralism of knowledge. Described by Daes (1994), IK is "... a complete knowledge system with its own concepts of epistemology, philosophy, and scientific and logical validity ... [which] can only be fully learned or understood by means of the pedagogy traditionally employed by [the] peoples themselves ..." (pp. 2–3). Further, Marlene Brant Castellano (2000) adds, "... knowledge valued in aboriginal societies derives from multiple sources, including traditional teachings, empirical observation, and revelation (p. 23) ... Aboriginal knowledge is said to be personal, oral, experiential, holistic, and conveyed in narrative or metaphorical language (p. 25)".

The philosophical foundation of IK prioritizes local geographies and relationships with the ecosystem over thousands of years. This is, however, not to say that the breadth of IK is made up of pockets of disconnected local or niche epistemologies, nor that Indigenous Nations stayed in one region and were static. Indeed, there is strong evidence that Māori wayfarers arrived on Salish territory (what is now the west coast of North America) long before Europeans. Recently, in a large genomic study conducted through an international collaboration (see Ioannidis et al., 2020), researchers found that "... Polynesians and Native Americans met at one point in history, and during that time people from the two cultures produced children with both Native American and Polynesian DNA" (Armitage, 2020). In a science communications article about the study, a co-lead researcher from Stanford University explained that the data shows, "... identical-by-descent segments of Native American ancestry across several Polynesian islands ... [serving as] conclusive evidence that there was a single shared contact event" (Armitage, 2020). The mounting DNA linkages of Salish (Native American) to Māori (Polynesian) ancestry is surprising to western scientists, but not to the Salish or Māori who have retained and preserved their oral histories; stories which now seemingly function to corroborate more formally accepted forms of "scientific" evidence.

The study referenced above is one example of how western academia is beginning to shatter notions that Indigenous people weren't global travelers pre-European contact; from the Bering Strait theory to broader human history, western science (WS) is learning that Indigenous oral histories are legitimate records. Indigenous histories and knowledge are encoded in songs, ceremonies and oral stories passed down from one generation to the next. The Haudenosaunee "social dances" are borrowed from other Nations; they are records of travel, allies, and observations kept alive and transmitted through song and dance. For example, the alligator dance carries accompanying oral histories of Haudenosaunee friendships with other tribes and ecosystems.

Indigenous Knowledge systems draw from within and from outside of neighboring tribes. This type of meeting and exchange between Indigenous communities across the globe has informed IK since time immemorial. Today, the resurgence of IK systems – including philosophies, epistemologies, identities, political governance, land-based practices, cultures, languages, and so on – weaves together multiple aspects of the fibers of Indigenous Knowledge methods and pedagogic practices of research. Whether

from health, environmental, cultural, or technological perspectives, IK research is intrinsically interdisciplinary, intersectional, and often inter-tribal. All of the natural world is interconnected, so too is IK. Indigenous Knowledge is "... a body of information about the interconnected elements of the natural environment which traditional Indigenous people have been taught, from generation to generation, to respect and give thanks for" (citing Jameson Brant in [National Aboriginal Forestry Association, 1996](#), p. 6). Ecocentric principles often bind Indigenous worldviews together regardless of region or Nation, whether from the Americas, Australia, Asia, or Africa. The real scientific question to pose is, how do Indigenous people from disparate parts of the globe hold common ecocentric worldviews, and why have "others" not held similar ontological truths throughout the ages?

Globally, IK has been shown to strengthen socio-ecological community resilience to the multiple stressors affiliated with large-scale environmental change. Following extensive engagement and discussions with community, researchers working with Six Nations of the Grand River (Six Nations) identified three primary areas of interest:

1. Bridging IK and WS [training];
2. Building youth resilience related to water security [wellness]; and
3. Exploring Indigenous laws through culture, language, and ways of knowing as essential to ecosystem management [governance].

Our project, termed *Ohneganos Ohnegahde:gyo* (Ohneganos) by the advising community knowledge holders, consists of leading experts in IK methodology who are working alongside western-trained scientists to co-create a holistic model of water research. The three Indigenous-led teams involved in the project (training, wellness, and governance) focus on the issues of addressing stewardship over time and crafting bilingual, relevant educational resources to foster resilience. Key deliverables of the project include developing mixed-method materials that are relevant for both a local and global audience (for instance, digital stories uploaded to YouTube¹) as well as establishing pathways for Indigenous secondary & post-secondary students to be trained in the braiding of Indigenous and western sciences. The overarching aim of our project is to holistically address cross-cutting and interconnected issues to create a "double dividend" that builds capacity and improves the resilience of the Six Nations community – acknowledging that Indigenous communities across Canada and beyond will stand to benefit from the knowledge, methodologies, technologies, and tools co-developed from the work completed.

Why water?

Indigenous communities in Canada are experiencing a water crisis that is exacerbated by climate change and has resulted in environmental, social, and health concerns. Water supplies are at high risk over a lack of access to water quality and quantity, water monitoring technologies (i.e., real time data and clear legal standards), and skilled management system operators. Inadequate infrastructure further increases the health burden in Indigenous communities.

Water crisis is widely experienced in Indigenous communities due to the "... ongoing struggle to have Indigenous voices heard in the decision-making processes that affect their lives, lands, and waters" ([McGregor, 2012](#), p. *abstract*). Research, capacity-building, and other supports are needed to advance a range of water-related topics such as governance, health, and expanding capabilities – including the development of Indigenous sustainability. The lattermost relies on IK, which is required to understand the water-health-legal nexus associated with water governance and is foundational to the mitigation of issues arising from inadequate water management. Such efforts and advancements necessitate thoughtful inclusion of diverse interests reflecting commonly held values in order to co-create and enhance innovative, sustainable, smart environmental management and training within communities that draws upon both IK and WS.

Indigenous Knowledge is increasingly recognized as a valuable source for adaptation and resilience-building in the face of impending environmental change and water insecurity – locally, regionally in North America (see [Finn et al., 2017](#)), as well as globally (see [UNFCCC, 2016](#); [Nakashima et al., 2018](#); [IPBES, 2019](#)). The Government of Canada's Federal Budget for 2017 underscored the priority of integrating IK in the country's pathway for sustainable growth to "... build a better understanding of climate change and to guide adaptation measures; enhance Indigenous community resilience through infrastructure planning ..." ([Government of Canada, 2017](#), p. 129). Similarly, the United Nations (UN) Sustainable Development Goals (SDGs) call on the governments of nation-states to "... [Goal 6.b] support and strengthen the participation of local communities in improving water and sanitation management" ([United Nations, 2015](#), p. 21).

With these goals in mind, Six Nations asked Ohneganos to develop specialized and accredited water management training, produce a bilingual virtual reality experience to disseminate co-created results from WS and IK, and create bilingual texts and educational resources for community knowledge mobilization. Knowledge mobilization on these issues involves listening, learning, educating, and training youth in the community in water management and governance to achieve self-determination and autonomy. In its entirety, the project consists of team leaders supported by dozens of community and university partners working in tandem to create strategic outcomes in Indigenous-led sustainable water monitoring and management.

Several challenges are inherent in these efforts. Establishing new, Indigenous-led pathways to post-secondary science and environmental streams is needed to build capacity in Indigenous communities, but at the moment this integration into postsecondary Indigenous Studies is struggling. This highlights the importance of capacity development, which includes the delivery of a cohesive

¹See [here](#) to view a YouTube playlist of digital stories published by Ohneganos.

and strategic stream of secondary school-level training that provides youth and community leaders with skills to respond to regional, national, and international developments impacting Indigenous water management. IK indicators of climate change, traditional governance principles, and determinants of wellness challenge the siloed approach of both community services and hyper-specialized university disciplines. Capacity development within university and community settings has – and will continue to – ensure long-term sustainable water stewardship, monitoring, and management.

Who we are

As Haudenosaunee peoples, Six Nations has an inherent responsibility to ensure that future generations can sustain their needs, and water is central to this ethos.

... For First Nations, water is a sacred gift, the life blood of Mother Earth, and all water, not just water for human use, needs protection. Through Indigenous ceremonies, laws, and protocols, First Nations have exercised inherent responsibilities to fulfill obligations to the Creator to ensure clean water for all living things since time immemorial ...

Longboat (2013, pp. 6–7).

Developing a Haudenosaunee-informed planning process to identify and manage surface waters and aquifers in Six Nations territories concerns land and waters outside of the government-imposed reserve boundaries of Six Nations. The area of concern extends to the Haldimand Tract (see Fig. 1) – which straddles the Grand River “... six miles deep from each side ... beginning at Lake Erie ... to the head of said river” (Johnston, 1964, pp. 50–51) – as well as beyond the tract, spanning numerous other disputed areas under “claim” by Six Nations, across the broader traditional territory of the Haudenosaunee.

Consumptive water takings, such as proposed commercial permits to remove groundwater² from the source with no return flow, are of significant concern to the Haudenosaunee leadership. Ohneganos consulted with the Haudenosaunee Confederacy Chiefs

Fig. 1 Six Nations Indian Reserve No. 40 (purple block) and the Haldimand Tract (shaded strip). Image created using Terrastories by Dawn Martin-Hill and Rudo Kemper.

Council (the traditional governing body of the Haudenosaunee) as well as Six Nations Elected Council and community members. Through meetings, roundtables, workshops, information sessions, climate change actions, and youth “No Nestlé” protest marches,

²See <https://www.wellingtonwaterwatchers.ca/nestle-faq>.

Ohneganos has shared research findings with stakeholders and established a broader online and social media presence.³ This has helped to create formal networks with multiple stakeholders from community, surrounding organizations, governments, and grassroots groups all concerned with local water management and regional management of the Grand River watershed. Six Nations departments (e.g., Health Services, Social Services Public Works, Wildlife Management Office, Environment, and Birthing Center), Haudenosaunee organizations (e.g., the Haudenosaunee “Protect the Tract”⁴ and Haudenosaunee Environmental Task Force), along with local primary and secondary schools all contributed in direct and indirect ways to Ohneganos research and knowledge mobilization. The Ohneganos Water Governance subteam built off feedback from community consultation and intensive engagement with all partners, identifying the emphasis on knowledge mobilization through focusing on the youth. When combined, such networks in service, education, and governance institutions act to secure the holistic maintenance and ecological integrity of water. This in-depth, interdisciplinary, and multilateral response to a community call to action has led to greater awareness of the issues, leading to pragmatic and impactful change within the Six Nations. For example, during the COVID-19 lockdown in Summer 2022, Six Nations Elected Council and Public Works department offered septic removal free of charge as part of relief to water access. Generally, the fee for removal is \$90.00 and funds must be paid in advance for removal of waste from septic and holding tanks. Another example is the removal of all Nestlé water bottles from Six Nations stores and services, given the company’s illegal removal of millions of liters per day from the local aquifer.

A key component to fulfilling Indigenous ethical research requires answering the question: “who will benefit?”. This is why developing capacity for youth to monitor and govern their *own* waters is built into all co-creation research proposals. Thus far, Ohneganos has secured micro-credentials for secondary students working on the research program in science, language, and technology with the goal of ultimately combining them to form a university credit through McMaster University (a nearby postsecondary research institute). Working toward the goals of accrediting and training Indigenous youth required collaboration with science and language teachers from local secondary schools. Collaborative efforts have involved embedding GIS mapping techniques, water testing, and ecological assessments into digital Indigenous maps as well as soliciting students to help create digital stories through on-the-water technology training, contributing to valuable data collection for Ohneganos. Further, youth from Six Nations in post-secondary were particularly keen to develop governance and leadership skills, so international-level opportunities were created that resulted in several youth attending the United Nations Permanent Forum on Indigenous Issues (UNPFII) and the Expert Mechanism on the Rights of Indigenous Peoples (EMRIP). At the former event, youth presented at a side-table workshop which has led to numerous invitations throughout the past several years. The opportunity to build youth networking and sustaining those relationships has elevated Six Nations voices in water related UN-affiliated engagements (Fig. 2).

Fig. 2 Ohneganos youth training in a holistic Indigenous-led approach to water management. *Left to right:* student mapping workshop (A), protest against Nestlé (B), and youth lead opening at UN (C).

³Website (<https://www.ohneganos.com/>), Facebook (<https://www.facebook.com/ohneganos>), and YouTube (<https://www.youtube.com/c/OhneganosOhnegahd%C4%99gyo>).

⁴See <https://www.protectthetract.com/>.

A primary area of concern identified by Six Nations' youth were anxieties and grief over climate change and water insecurity. After retaining additional funding to expand Ohneganos in 2018, a community-led mental health research team was developed. A critically important determinant and indicator of health is access to clean water. Water insecurity negatively impacts quality of life and wellness, particularly mental health. Through surveys and interviews with Six Nations Health Services, Birthing Center, and youth focus groups, lack of access to clean water was found to be a significant stressor in day-to-day living. Further, youth experienced multiple barriers in harvesting the food and water they require for cultural continuity, thus impacting well-being (Chandler and Lalonde, 1998). If cultural ties to hunting, fishing, and ritual are impeded through environmental degradation, it further adds to stressors that affect overall health and wellness (Kirmayer and Valaskakis, 2009; Majeed and Lee, 2017).

Recent literature on environmental grief proposes that climate change creates environmental uncertainty, which can make youth more susceptible to depression and anxiety in general, while also specifically impacting other stressor sources, such as poor water quality and food insecurity. A recent study using data spanning several decades found that suicide rates are rising along with increasing temperatures because of global warming in both the United States and Mexico (Burke et al., 2018). Indigenous youth mental wellness must be centered in land, language, community, cultural identity, and empowerment (Martin-Hill, 2009; Mussell et al., 2004).

With this knowledge mind, Ohneganos youth lead, Makasa Looking Horse, spearheaded several youth-led initiatives for the project, including: organized climate change community actions, water protector teach-ins, No Nestlé marches, Youth Rise community leadership events, school art contests (see Fig. 3), and a tree giveaway for Earth Day; facilitated youth participation in the Two Row Paddle on the Grand River⁵; and created a renowned video podcast series called *Ohneganos: Let's Talk Water*.

Ohneganos supported outreach activities with youth designed to empower and elevate their voices. Through a partnership with Six Nations Social Services, Ohneganos provided schoolchildren with art supplies and asked them to express their views about water. This activity was highly successful and insightful, demonstrated by the submissions illustrated in Fig. 3. All of the activities designed by Ohneganos prioritize the empowerment of youth voices. By showcasing their work and written ideas and sharing their experiences in water protection, knowledge mobilization was advanced in a meaningful way, positively impacting youth-led water actions. This activity, which engaged youth as well as frontline health workers and Elders, served to foster community resilience in youth mental health.

Fig. 3 A collage of submissions from the “Water is Life” Ohneganos art contest in six nations.

⁵See <http://tworowonthegrandriver.com/>.

Bunch et al. (2011) suggest “... actions that address both biophysical and social environments have the potential to create a ‘double dividend’ that improves human health ... while also promoting sustainable development” (p. 2). From youth and community consultation to date, specific research tools have been identified that aim to create such a double dividend, including:

1. The need to develop a coordinated survey tool that includes information on water anxiety, perceptions of water quality, access to perceived healthy water and understanding of burden of cost, positive water actions, positive experiences with social justice, and resilience in youth.
2. The need for the documentation of water stories, emphasizing youth-led positive action as an open-access knowledge mobilization tool.
3. The need for a youth-informed resilience communication tool, such as a mobile application, that incorporates access to archives of youth stories, and serves a role for further water advocacy, youth agency, and a possible intervention in coping with water-related stressors.

In addition to developing a mental health mobile application, the ultimate goal is to create a multifunctional and “living” web platform that presents Ohneganos research while also facilitating digital access to all of the project’s co-created findings and tools.

Kayaní:yo (A good path)

Dissemination of science through the arts is in step with ancestral transmission of knowledge, encoded through song, dance, ceremony, and stories in our language. True to Haudenosaunee ways of knowing, the Ohneganos research project sought to co-create community stories that weaved traditional knowledge and western scientific data through visual, sensory, and emotive mediums. Communicating the research rationale, methods, and findings required a continual dialogue with numerous sectors of the community, engaging and communicating through various modes, such as by developing an immersive and interactive virtual reality (VR) experience and by 3D-modeling and data visualization. Another key aspect of developing a tangible and impactful data environment was integrating real-time water sensing data within a decolonial place-based mapping program called *Terrastories*, creating a holistic interactive map that houses both Haudenosaunee knowledge and technical water data. In this vein, the community also participated in the linguistic and cultural mapping of waterways as a method of decolonizing the local geography and creating an Indigenous map.

Yothá:te is a figurative “path” that implies a warrior’s intentions to be of aid – to be helpful; something which is considered as *kayaní:yo* (“a good path”) as it protects what our ancestors valued the most. In this way, co-creation approaches to science is putting our bodies back on the land and waterways, rediscovering our ancestral knowledge which has accumulated over thousands of years, and translating it to solve modern colonial-induced ecological problems. The elevation of IK, enhanced with WS and modern technologies, helps advance the protection of water, animals, and land ecosystems. The creation of ally networks and the application of scientific pluralism – when deemed appropriate – is, in fact, *Warrior Science*; it is clearing the *yothá:te* through rebuilding and nurturing passions, spiritual connections, and peaceful relationships to mitigate the climate crisis and rehabilitate biodiversity loss.

The climate crisis is leading to a period understood in scientific circles as the sixth mass extinction. The previous mass extinction was defined by the Cretaceous-Paleogene extinction event, during which the dinosaurs, along with thousands of other species, perished. A notable difference is that the current period of extinction we are in is manmade; it has not been caused by a natural event. Accordingly, anthropologists argue and geologists debate over if we have moved out of the Holocene and into a third Quaternary epoch, the *Anthropocene* (Zalasiewicz et al., 2011). However, it could be further posited that this would be a misnomer for the following reason: the United Nations Department of Economic and Social Affairs is clear in their analysis that Indigenous peoples, who are also human beings and part of the *anthropos*,

... account for only around 5 percent of the world’s population, [yet] they effectively manage an estimated 20–25 per cent of the Earth’s land surface. This land coincides with areas that hold 80 per cent of the planet’s biodiversity and about 40 per cent of all terrestrial protected areas and ecologically intact landscapes. Indigenous peoples therefore play a key role in efforts to protect the planet and biodiversity.

UN DESA (2021, p. 1).

Hence, perhaps this proposed epoch should be renamed the *Colonialcene*, for it is the imperialism of the past five centuries that has led to the great extinctions of the Holocene. Colonialism and western industrialism have driven climate change and the introduction of invasive species, accelerating the loss of life as plant and animal habitats disappear or are disrupted by new species. In fact, Michael Novacek, Senior Vice President of Science at the American Museum of Natural History, has stated, “... some biologists think that the current rate of species loss is probably a thousand times what the normal rate is ...” (AMNH, 2015). What mainstream scientific literature fails to acknowledge is identifying the socio-political driver of “human activity” that has led to the global crisis of biodiversity loss.

Co-creation has its challenges, which is often nested in the arrogance of western colonial epistemological constructions of the natural world and its peoples. Indigenous ecological knowledge (also commonly referred to as Traditional Ecological Knowledge or TEK) has been, and continues to be, dismissed by data-driven western scientists – even when the data is speaking clearly in global studies that are emphasizing the validity of Indigenous ways of knowing,

... this report recognises the value of diverse forms of knowledge such as scientific, as well as Indigenous knowledge and local knowledge in understanding and evaluating climate adaptation processes and actions to reduce risks from human-induced climate change.

IPCC (2022, p. 9).

Our oral histories tell us that we have experienced planetary climatic changes and cataclysmic events throughout history, and we have survived. We have stories about the Ice Age, the Great Fire caused by thunderers that chased the scary animals underground, and the Great Floods. In fact, Elders have recited and warned for nearly a century that settlers are creating an unsurvivable world for humans (Akwasasne Notes, 2005). IK draws upon this intellectual legacy while reinvigorating our language, stories, and ancestral wisdoms. By creating alliances with activists, artists, scientists, and leadership we catapult our voices into the consciousness of mainstream society. We carry out *kayaní:yo* by utilizing every tool in the toolbox, from social media to water monitoring sensors, VR technology, and scientific data circles. In doing so, we do more than decolonize, we lead the way. The overarching intention of Ohneganos was to demonstrate the successful harmonization of IK and WS by co-creating an enduring legacy of “tools” that target a holistic assessment of the environment, underpinned by Indigenous conceptions of human wellness and quality of life.

Equity in scientific inquiry: Indigenous Knowledge dismantling structural barriers

In an article titled *Why Indigenous Studies Matter for Natural Sciences Students* Hughes (2018) summarizes her work by stating,

... This article encourages students of the natural sciences to remember the importance of indigenous knowledge. Indigenous peoples work with scientists to share traditional ecological knowledge that has been honed over generations and allows for increased stewardship of natural resources. Indigenous knowledge should be integrated into university programs and Western scientists need to collaborate with indigenous groups towards conservation efforts.

The calls to include Indigenous ecological knowledge in the natural sciences appear to be a good *yothá:te*, but is it a *kayaní:yo*? There is the matter of colonialism framing dialogue between westerners and Indigenous people and, as a result, the potential for exploitation, appropriation, co-opting, and whitewashing IK is extraordinarily high. The hierarchical nature of academia and science is oppositional to IK, with structural racism in place that has been acknowledged by numerous Canadian inquiries (see RCAP (1996), TRC (2015), MMIWG (2019)). Yet, despite a chorus of calls to action to remove such structural barriers, nearly every recommendation on this matter has been ignored by the Canadian government and the general public.

Researchers from community, the local immersion school, and Indigenous undergraduate students – all who are part of the *TEK team* – have exhibited the Haudenosaunee ecocentric mixed-methods pedagogy through the recruitment of local stakeholders, such as service department representatives and secondary school teachers. Students and teachers working with the Ohneganos team are funded to create resources and programming, provide sustainable capacity and knowledge mobilization, and carry out research. Importantly, these students are also being credited by partners from McMaster University and Mohawk College (and potentially more local institutions; the opportunity is open to all who express enthusiasm and willingness to create and engage in the delivery of mixed-method programs). There have been preliminary agreements to formally accredit existing community researchers and develop a pathway for secondary students to pursue post-secondary environmental studies and water management programs that integrate experiential learning. An example is McMaster University Continuing Education agreeing to work on a pathway to credit the local language immersion school in Six Nations (Kawenní:io/Gawení:yo Private School) and students from the Six Nations Polytechnic the STEAM academy; teachers and educational assistants from which are assisting in current and ongoing knowledge co-creation and program development. These efforts include developing water-related digital stories, mapping traditional harvesting activity on water, and co-creating IK-led material in a bilingual text on Haudenosaunee Science. Mohawk College, McMaster University, and Six Nations education leaders have agreed to form an ad hoc committee to work together on multi-level accreditation pathways and programming to sustain forward solutions.

The goal of Indigenous-led research moves beyond single questions and answers; we must use research resources, expertise, and networks to solve community problems *while also* answering “the questions”. One way to develop capacity is by establishing sustainable ways of teaching IK and WS to train environmental researchers in ecological mixed-method approaches prior to engaging in research projects. Currently, the Indigenous scholars working on Ohneganos are burdened with on-the-job training of graduate students and faculty (e.g., professors from engineering, biology, health sciences, etc.) which imposes stress on all parties.

There is also a lack of equity in knowledge production in ecological research. Research contributions by Six Nations secondary students, undergraduate students, and knowledge holders are original and highly valued, but only one party receives scholarships and research funding resulting in Doctorates or Master’s accreditation. Indigenous Knowledge has no such support, scholarships, or funding equal to their partners and minimal accreditation; yet their contributions are imperative to the overall project design, implementation, and dissemination. Future research engaging Indigenous ecological knowledge should be strategic and thoughtful (with cumulative accreditation) to ensure an outcome that formalizes an IK/WS program that is operated by Indigenous Studies departments within institutions, as well as the people and community. This would address some of the current issues in academic institutions. Currently, the research funding, academic achievement, and unequal status of non-Indigenous researchers working on

Indigenous research projects gains awareness by community partners; this is discouraging, and community partners become disengaged overtime. As described, the IPCC, UN DESA, and other UN agencies value Indigenous ecological knowledge, but provide little means of structural support to elevate or advance IK-led research. Another significant barrier in equity is lack of practical bilingual teaching tools – from secondary school resources through to university level texts. As described, Ohneganos has been working to fill such gaps by developing resources and organizing them into a series of learning materials targeting both secondary and post-secondary students.

A primary example of the incredible contributions of Six Nations researchers is the Indigenous mapping of Haudenosaunee lands and waterways using *Terrastories*. The TEK team is carrying out GIS digital and decolonial mapping with the help of consultants from *Digital Democracy*⁶ as a way of storying our territory. Students and community researchers are assisting in developing Haudenosaunee placename maps that include digital stories, local oral histories, and traditional ecosystem inventories. The legacy of such an expansive Indigenous map will build on the seminal work of the *Decolonial Atlas*⁷ by focusing on Haudenosaunee heritage; the placenames of waterways, lakes, and aquifers; and by attaching both IK and WS data (e.g., historical cultural information about those bodies of water and water monitoring and climate change data). The digital archive accomplished through mapping will provide a teaching tool with language accessibility in both Mohawk and Cayuga. The digital maps will assert Haudenosaunee sovereignty and contest colonial boundaries. The information populating the map has been collected by secondary students with support from the Ohneganos Community Mapping Facilitator, Chris Martin, and would easily merit, at minimum, a Master's or Ph.D.; therein lie the inequity of knowledge production and accreditation. Aside from the programming and accreditation being co-led by Ohneganos, thus far we have only been able to produce ad hoc Certificates of Completion for student contributions with the support of McMaster University Continuing Education. This is a start, but this shows how community members receive no such recognition by institutions in community-research partnerships and demonstrates the need for institutional advancement in accreditation.

Key principles exemplified by the Ohneganos project include: a) defining research goals that are directed by Indigenous communities, and b) designing and implementing the co-creation of research, content, materials, and tools by observing ethical guidelines such as the *Tri-Council Policy Statement 2 Chapter 9: Research Involving the First Nations, Inuit, and Métis Peoples of Canada* (see [Government of Canada, 2018](#)) and the *Principles of Ownership, Control, Access, and Possession* (see [Schnarch, 2004](#)). Together, these guiding principles work to uphold the inherent rights of Indigenous Peoples (see [UNDRIP, 2007](#)) and Indigenous data sovereignty, helping the research unambiguously exemplify the phrase “nothing about us, without us”. Further, ecologically-informed community-developed capacity to monitor environmental health will build on foundational mixed-method pedagogy and outcomes by facilitating targeted dialogue between Western-trained scientists and Indigenous experts in all fields. Developing pathways to empower Indigenous communities to manage control over their water as a primary indicator of wellbeing is a crucial mechanism for achieving self-determination. Creating such pathways for Indigenous youth has had positive impacts on their careers and aspirations and created community pride in the work of the youth.

Reconnecting youth to waterways and tradition

Well-being among Indigenous people is firmly rooted in the connections to the land, the sea, and fresh waters, “... as a subsistence society, living off the natural resources of the land was fundamental to the social identities [of Natives] ... [an] intimate relationship in the reciprocal nature of caring for the land ... as it cares for the people, much like a family bond” ([Kanaŋiaupuni and Malone, 2006](#), pp. 289–290). Recognizing this, the TEK team supports the Two Row on the Grand River, a nine-day canoe paddle and symbolic enactment of the original Two Row treaty (see [Parmenter, 2013](#)) down the entire length of the Grand River in Ontario – fully equipped with educational events, traditional teachings, interactive dancing, storytelling, and sharing circles. Through involvement with the Two Row paddle, Ohneganos supports youth capacity-building by facilitating experiential mixed-method learning – on the water, about the water.

Knowledge mobilization and community engagement

The coronavirus pandemic interrupted many aspects of the Ohneganos project, from collecting water samples in homes to youth outreach and training. However, it also forced our team to think creatively and embark on a new journey of discovery. The *Ohneganos: Let's Talk Water* (Let's Talk Water) video podcast is an ongoing project hosted by Ohneganos youth lead, Makasa Looking Horse, with the help of Ohneganos full-time student staff. The production – which has been immensely successful in data sharing, awareness building, and co-creation – was a response to the COVID-19 lockdown and acted as a means to continue dialogue with the community, share research results, and elevate youth voices. Leveraging the power of social media, the show was hosted live on Facebook and YouTube with an average number of 600 views over the first 19 episodes (with a maximum of over 1000 views!). The Ohneganos Facebook page also skyrocketed from 54 to 1100 likes/follows. Importantly, Let's Talk Water also served as a safe,

⁶See <https://www.digital-democracy.org/>.

⁷See <https://decolonialatlas.wordpress.com/>.

innovative, and real-time methodology for collecting data, providing training, and disseminating research results. It required training of our all-female student team – being taught by consultants on cinematography, live productions, and film and sound engineering – as well as required sensitivity in recruiting and hosting a diverse set of guest speakers and participants. Let's Talk Water relied heavily on Makasa's network of well-known Indigenous singers, activists, Indigenous Knowledge holders, change-makers, and scientists to provide fresh and exciting content. The "science" was weaved into these conversations in a way that made sense to Indigenous audiences, though it is recognized that it may have been a bit confusing to the western-trained team members. The tensions of colonialism are never held far at bay in "co-creating" and can be, at times, draining for all parties. As such, co-creation requires an ongoing level of patience, understanding, and perseverance.

Public dissemination matters

The attention Let's Talk Water garnered in raising Indigenous voices poured in outreach from Vogue, Chatelaine Magazine, Yes! Magazine, Aboriginal Peoples Television Network, Vice News, CBC News and many others. The visibility then generated interest from multiple Indigenous communities across Canada, the United States and elsewhere because of Let's Talk Water's exploration of youth experience and the numerous consequences associated with water insecurity in Six Nations and other First Nations communities.

Youth represent the leading demographic in Indigenous communities and, as such, they are the driving force. In an era of climate change, Indigenous youth carry an added stressful burden – the burden of safeguarding the planet. Let's Talk Water is youth-led program giving a voice and platform to Haudenosaunee youth, as well as inspirational leaders from across the globe on the front lines of environmental justice, resistance to oil & tar sands, MMIW, health, and healing. Witnessing overt destruction to Indigenous lands and waters is an ongoing assault on Indigenous being. A recurring theme of Let's Talk Water repeated routinely by Makasa is that Indigenous youth need to connect more than ever while experiencing overwhelming ecological degradation and exploitation by corporations. In an upcoming film on ecological grief, Makasa describes the continued assault on local waters and land by corporations as "a million little cuts on my soul",

... whether it's Nestlé taking our precious water from the Grand River watershed, or my father's waters and lands marred by the Dakota Access Pipeline [DAPL], corporate greed and the extractive resource industry is devastating our planet ... [yet] we have found out that Nestlé is leaving Canada, the DAPL has been ordered to stop production until a review is complete and other pipeline projects halted, all due to youth activism and allies. The efforts of young water protectors have made impacts, but we have no definitive platform to share our experiences – such as those fighting at Standing Rock.
Looking Horse (Publication Pending).

In 2021, *Ohneganos: Let's Talk Water* won the David Suzuki Foundation's Future Ground Prize, People's Choice Award. Ohneganos was able to market the project's research to an audience that cares about Indigenous youth, climate change, and water security. At the same time, it also engaged people who aren't necessarily involved in academic science projects or who aren't Indigenous youth. The video podcast was a tremendous accomplishment while the community was reeling from the pandemic lockdown and demonstrated the strength and determination of a community-led research project, illustrating how incredibly resilient Indigenous communities are in the face of adversity.

All co-creators, Indigenous and non-Indigenous alike, rose to the occasion in accessing co-workers, allies, scientific colleagues, and community to build the Let's Talk Water social media knowledge mobilization platform. In each episode of Let's Talk Water, the viewers were routinely reminded of the era we are operating within; the sixth mass extinction – the *Colonialcene*. In battle, the meaning of *kayaní:yo* (a good path) can also mean "things are running along peacefully". Similarly, *yonkwarihwani:ron niyonkwarihò:ten* translates as, "we are steadfast in our ways of being". When our ways of being are not steadfast, we remove ourselves from that *yothá:te*, requiring time to reflect on ways to achieve peaceful relations without damaging our ways of being. The warrior is simply a skilled worker for the people to benefit their health and well-being; a worker with courage who is highly valued, paying close attention to the messaging in an effort to balance positives and negatives. Co-creation requires warriors who are willing to make some sacrifices so the people and creation may live, working through the tensions, discomfort, unequal power relations and social capital to remain on our *yothá:te yonkwarihwani:ron niyonkwarihò:ten*.

Introduction

In the current era of the *(critical) social justice turn* in education research and practice, epistemic diversity has been increasingly promoted, discussed, and problematized (e.g., Xu, 2022; Piller et al., 2022). China, the context of this article and one of the world's most diverse countries (Yuan, 2018), has also been active in trying to push for her own epistemic inclusion globally, as can be seen in the use of discourse instruments such as "Chinese cultural confidence" (文化自信) or "world-class education with Chinese characteristics" (具有中国特色的世界一流教育) in Chinese education (Dervin, 2022). Often, the ideas of "confidence" and "Chinese characteristics" remain unproblematised in relation to Mainland China and its 56 official Minzu (民族) "ethnic"¹ groups, especially in relation to indigenous knowledges.² This article aims to complement these discussions by focusing on such knowledges, from teachers' perspectives, in Chinese secondary education.

In Chinese academic circles, there is a special field attached to Minzu groups called Minzu education (中国民族教育), which, for at least the past 50 years or so, has endeavored to do research on and e.g., prepare teachers for working with different Minzu groups (Sude et al., 2020). Although research on some aspects of Chinese Minzu education has been discussed internationally (often under "Western" guises such as American multicultural education, see e.g., Wang, 2021), to our knowledge, none of these studies have looked at it from the lens of epistemic diversity and indigeneity.

This paper, which is embedded in the two authors' long-term cooperative work on Minzu education and interculturality (e.g., Dervin and Yuan, 2021), first problematizes the notion of indigeneity in relation to the Chinese Mainland by exploring how it is (not) used and offers a linguistic discussion of words related to the notion in Chinese. The notion of Minzu is then presented and offered as an epistemic complement for the English word *indigenous* in relation to knowledges, alongside with a short review of previous research on the topic. The chapter ends on an analysis of interview data collected among Chinese middle school teachers in a Minzu area (Inner Mongolia, Northwestern China) about their engagement with Minzu (indigenous) knowledges in their teaching. This serves as a case study and is not meant to be generalized to other contexts of Minzu education within Inner Mongolia and in the Middle Kingdom as a whole.

Problematising *indigeneity* for the context of Mainland China: a critical language review of the word *indigenous*

In this first section we discuss word use in Chinese and English. We note that both media and academic discussions of general Minzu affairs have been tense in the West, especially since the beginning of the 2019 pandemic in the midst of an increasing economic-political polarization of the world. These discussions appear to be systematically based on "Western" and especially US-led ideological takes on "race" and "ethnic" relations, which do not leave enough space to explore how the Chinese themselves engage with the notion of Minzu in academia, education and society at large (see Dervin and Yuan, 2022). Word use in different languages and the connotations of specific terms to discuss e.g., *diversity*, *majority/minority*, *indigeneity*, must be examined here to ensure that we are not simply "copy-pasting" ideological takes onto another context. We believe that this also helps us avoid universalizing the way we see self-other in specific societies. What follows is not meant to be read as "in defense of" China. As such, like all

¹The word "ethnic" is between inverted commas to indicate that the connotations of the English word, which are unstable worldwide, considering the very different economic-political contexts where it is used, may not reflect the specificities of the Chinese word Minzu. As a reminder, the English word "ethnic" was used first to refer to individuals who were not followers of either the Christian or the Jewish faiths.

²Since other parts of China such as the Special Administrative Region of Hong Kong do not follow similar patterns of classifications of "ethnic" groups, we do not discuss their specific cases here.

other countries, China is struggling to ensure equality, equity and social justice among its 1.4 billion inhabitants and many “Western” and Chinese scholars have attempted to describe such struggles in their own terms (e.g., Hao, 2020; Wang and Jiang, 2021; see Pasternak, 2020 about the context of this study, Inner Mongolia). Our goal here is to send a reminder concerning *multi-lingual* and *ideological* ways of speaking and interpreting other contexts to those of us working on indigeneity from international (comparative) perspectives in education.

Let us start with etymology. The English word *indigenous* derives from Latin *indigena* for *sprung from the land, native, in-born in a place*. It is based on Old Latin *indu* for *in* and *within* as well as *gignere* for *to produce, to beget*—with the latter derived itself from Proto-Indo-European for *to give birth*, and the idea of *familial* and *tribal* groups. In Chinese *indigenous* translates as 土著 (tǔzhù), with *native* and *aboriginal* as synonyms in English. Each of the two characters have the following meanings: 土 is *earth, dust* and 著 can translate as *writing* but also *receive, suffer, and make known* (among others). The definition of the word seems to include the features of being a “native”, having lived in a specific area for generations, and having faced invaders and colonizers (Zhang, 2002). It is thus very close to the United Nations definition of indigenous. This definition often includes at least three groups in the Chinese definition: *Aboriginal Australians, Native Americans* and *African Indigenous groups*.

Our next interest is in how the word *indigenous* has been used in recent international research in relation to China, with many different uses having been noted in English. The main strand relates to different fields of research and applies the word *indigenous* to China as a whole (in chronological order):

- Indigenous roots of modern Chinese psychology (e.g., Jing and Fu, 2001);
- Chinese indigenous swine (Kang et al., 2015) and goat (Yue et al., 2017) breeding;
- Theorizing China’s indigenous innovation capabilities beyond a traditional Western-centric theory of innovation (e.g., Vinig and Bossink, 2015). The Chinese term used in the global literature is 自主创新, which means *autonomous innovation*—*autonomous* referring here *to act for oneself*;
- Indigenous traditions of Chinese religions (Zhuo, 2017);
- Cultural roots in indigenous Chinese communication theories, including visualizing and modeling Chinese cultural factors like wind, grass, and water (Tian and Yu, 2022).

Some of the literature does use the word *indigenous* to refer to the knowledges of specific (“ethnic”) groups and communities within Mainland China (in chronological order):

- Indigenous knowledge of dye-yielding plants by Bai Minzu communities in Yunnan (Southwest) (Fan et al., 2018);
- Indigenous psychology among the Yi Minzu group in Southwestern China (Ting et al., 2019);
- Indigenous knowledge in integrating scientific and indigenous knowledge for community-based disaster risk reduction, e.g., taught by oral form through storytelling, in the Ningxia Hui Minzu Autonomous Region in Northwest China (Wang et al., 2019);
- Ethno-ecological knowledge of indigenous people regarding the use of ecological cues to conduct seasonal activities in relation to climate change in Tashkurgan, Xinjiang Province, near the Pakistani, Tajik, and Afghani borders (Yang et al., 2019);
- Indigenous knowledge in forest and wildlife conservation by Buland People in Yunnan Province (Su et al., 2020).

One notes that the fields of research include communication studies, forestry, psychology, (among others) but that, for example, no research on education has made use of the word *indigenous* in the English language, preferring another problematic term: “ethnic minorities”. Before we offer more details as to why in the next section, we comment on one paper that offers further elements to the linguistic discussions of Chinese equivalents to *indigenous* in Mainland China.

In *An Alternative to the “Indigenous” in Early Twenty-First-Century China: Guizhou’s Branding of Yuanshengtai* Luo (2017) examines the emergence and use of the Chinese concept of 原生态 (yuánshēngtài) through cultural industries and marketization at the turn of the 21st century. The concept translates as *original ecology* in English (原 means *original, former* and is used in the Chinese word for *aborigines*; 生态 means *ecology*). Luo (2017) argues that this rich term is difficult to translate properly in English and that some of its translations are problematic (e.g., *pristine* or *primitive*). The term refers to distinctive “native” and “original” cultural elements that have survived for hundreds of years, including dance, singing, “freehand” landscape painting but also housing, food and ecological protection. For example, folk songs such as *Manhan tunes* (a mix of Mongolian and Han songs), *the Twelve Muqams* (ancient Uigur music, combining music and dance) are considered as 原生态. Academia, the media and the cultural industry have made ample use of this term over the past decades in China. Assisting the development of the local economy through 原生态 is also often noted (Luo, 2017). Both ethnic and rural peoples from certain parts of China (e.g., highly multi-Minzu provinces like Yunnan on the country’s southwestern frontier, with over 40 million inhabitants) seem to be included in its use. We also note that Luo (2017: 74) is critical of the use of 原生态, calling it “romanticized symbolism (...) which conflates ethnicity, rurality, and nature, has come to be expressed through consumer desire”. She adds that the use of the concept could disfranchise discussions of historical and political issues, by emphasizing political economy and intellectual production (Luo, 2017: 90). The important issue of who represents who in the use of the concept is also put forward by Luo (2017). However, in her article (2017), she also shows that many of the discussions about environmental sustainability and heritage around the concept are very much reminiscent of international discussions of conservation around indigeneity. Finally, she maintains (2017) that the positive tone of 原生态 has contributed to e.g., valorize Chinese Minzu groups for their environmentally based knowledge and practices in China today. The notion of Minzu (民族), a central “companion” term to *indigenous* in the Chinese context, is discussed in the next section. We propose to use the pinyin romanized version of the notion in English, instead of *indigenous*, in our chapter.

Minzu as a companion to indigeneity?

In 2016 Hathaway wrote a paper describing how global environmental organizations had “unintentionally smuggled” the idea of *indigeneity* into China, although the Middle Kingdom does not use this notion to describe its diversity of peoples. As a reminder, there are many Chinese equivalents to the word and none of them seem to fit the polysemic English term. It is important to note at this stage that China *does* support indigenous rights internationally as stipulated by the United Nations (China signed the United Nations Declaration on the Rights of Indigenous Peoples in 2008) but, as Hathaway notes (2016), the country does not apply the notion to itself, using the word *Minzu* (民族) instead to describe itself as a land of “ethnic groups”. In his paper Hathaway shares his views on the question (2016: 2):

In the course of my research over the last twenty years, I have been asked many times: are there indigenous people in China or not? My answer has always been that it depends. The term is almost always understood as a natural category and the expected answer is either affirmative or negative: do any groups in China meet the criteria commonly expected of indigenous peoples? I argue that indigenous status is a political category. Identifying with the category of indigenous is a political strategy as much as it is an identity.

In a similar vein, in *The definition of indigenous peoples and its applicability in China*, Wang (2015) questions the applicability of the concept from an international law perspective. Commenting on the uncertainty of the definitions of indigeneity around the world, the complexity and specificities of the *Minzu* situation and the rejection of the term *indigenous* by Chinese authorities to talk about China, Wang urges us to clarify the Chinese terms in relation to Chinese *Minzu* (which he himself calls “ethnic minorities” in English...).

In her discussions of 原生态 (“original ecology”) in the aforementioned article, a term in Chinese used to refer to “indigeneity” from within, Luo (2017) also introduces the notion of *Minzu*. She reminds us that the term is polysemic in English and that it has been translated as *nations*, *nationalities*, *ethnicities*, and even *races* (Thomas, 2022; Dervin and Yuan, 2021; Dikotter, 2015). According to Luo (2017), 原生态 is often used to promote the ideas of “harmonious multiculturalism” and “unity in diversity”, which are also central discourse components of Chinese *Minzu*.

Equivalents to the word *indigenous* are thus many and varied in Chinese. We have also noticed that some Chinese might use it in English, without being aware of its differing connotations and ideological bases. They might use it to refer to all Chinese and to specific *Minzu* groups. In a similar vein, the same people might use the word *nationalities* in English to refer to *Minzu*. The fact that the authorities do not use the polysemic English term of indigenous to refer to the diverse situation of China does not mean that the Middle Kingdom disregards *Minzu* “minorities”. We now turn to the very word *Minzu*.

From a research and political perspective *Minzu* (民族) appears to be the closest to *indigenous*. Let us share a few more pieces of information about the notion. The Chinese word is composed of characters that mean “folk or common people” (*min* 民) and “consanguinity or lineage” (*zu* 族); in other words: *community of folks with a common origin*. China is officially a unified country with a diverse *Minzu* composition, where rights for *Minzu* groups are protected by laws and inscribed in the *Constitution of the People’s Republic of China* (1982). Current *Minzu* policies favor fostering a strong sense of community for the Chinese nation to ensure *Minzu* unity in diversity. The Chinese government recognizes 56 peoples of *Minzu* groups, with one group representing the *Minzu* “majority” (Han). It is important to note that about 800,000 people are still not recognized as being members of specific *Minzu* groups. The largest non-Han *Minzu* groups include e.g., Uyghurs, Mongols and Tibetans. The 55 *Minzu* “minority” groups represented around 8.9% of the population in 2020 (National Bureau of Statistics of China, 2021). Since China shares borders with 14 countries, a vast majority of *Minzu* groups are located on borders. Regional *Minzu* autonomous areas include for instance the Inner Mongolia Autonomous Region and the Xinjiang Uyghur Autonomous Region. Although Chinese citizens may have different mother tongues (e.g., Uyghur, Tibetan), most speak and study Mandarin Chinese, China’s common lingua franca—as much as in “Western” societies different languages and dialects might be spoken but one or two languages are used for official and educational purposes by all. It is important to say that economic development is central to *Minzu* affairs, with e.g., many economic stimulus programs for different *Minzu* groups having been established by the government.

Finally, we note that the notion of *Minzu* is included in the (2022) book *Changing Theory* (Menon, 2022), where the editor and authors chose linguistic concepts from 16 languages from Africa, the Arab world, Asia, and South America to open up global and multilingual conversations on social theory, beyond Euronormality (Kaviraj, 2009) and away from Euro-American formations (Menon, 2022). In the introduction to the book, Menon (2022: 2) makes an important point: “It is not about rendering visible words and ways of thinking across the Global South through mere translation within a monolingual space, which entrenches the politics of English as a universal language of rendition (...). A true conversation must engage with the nuances and hardness of multilingualism as much as the possible quiddity of concepts”. In using the notion of *Minzu* (instead of the polysemic English word *indigenous*) in the rest of this chapter, we wish to contribute to render the specificities and complexities of this notion in the English language, as a complement to discussions of indigeneity in education.

Minzu knowledge in Chinese education

The focus of this chapter is on the potential use of “alternative” Minzu knowledge in STEM education in a specific area of China (Inner Mongolia). This subsection problematizes the idea of Minzu knowledge, considering both discussions of epistemic diversity and indigenous and traditional knowledge. Before we do so, we provide a short review of how these issues have already been considered in research on Chinese (teacher) education.

Let us start with the field of *Minzu education* in Chinese Mainland (Sude et al., 2020), which is mostly unknown to international audiences. Based on anthropologist Fei’s (1989) theory of unity in diversity, Minzu education aims to acknowledge the diversity of different groups while promoting their togetherness and Minzu solidarity. For Wang (2021: 112), in China, “celebrations of cultural diversity must be built on support for unity”. A variety of preferential policies have been established to ensure educational opportunities and the socio-economic mobility of members of all Minzu groups. For example, students from certain Minzu groups, such as the Mongolian Minzu group under review in the next section, get bonus points in high school and college entrance examinations. Kong and Yu (2019) summarize the characteristics of Minzu education as follows: Equality and national solidarity as fundamental principles, as well as mutual assistance between Minzu groups and unfailing commitment to bilingual education and teacher quality. They note however the following problems in Minzu education (Kong and Yu, 2019): An unequal power relationship between certain Minzu groups, e.g., patriarchal relationship between Han (the so-called “majority”) and some Minzu groups; one-way assistance; but also disconnect between language teaching and cultural competence; support for Minzu minority language, but not Minzu minority culture.

A few review articles have been published about Minzu education in English between 2013 and 2022 detailing what has been done in this field. For example, in 2018, Wei Wang published a review paper on education and ethnicity in China covering the period 1990–2014. Wang’s focus is on how these topics were researched in Chinese in top journals published in Mainland China (Wang, 2018). The scholar identified six themes in 431 journal articles: *educational policy*, *multicultural education*, *minority cultural heritage in school*, *ideological-political education*, *multilingual education*, and *teachers and teacher education*. He notes that the inclusion of cultural heritage in curriculum settings seems to dominate such studies while teachers and teacher education are limited (Wang, 2018). He adds that the dominating theoretical trend in the papers is “multicultural education” (its “American” branch). Another example of a review is from 2020 with Liu et al. (2020) review of research from 2000 to 2018 about what they refer to as “Chinese multicultural education”. The data used for the review consists of 179 journal articles published in Chinese (157) and in English (22). Their results are categorized into:

- Theoretical discourses on Chinese multicultural education;
- Multicultural curricula and instruction;
- Students’ perspectives in multicultural contexts;
- Multilingual education and language policy;
- Citizenship education;
- Multicultural teaching and teacher education.

The authors discuss for example how some authors such as Teng (2003) have tried to propose a form of multicultural education model for working with Minzu. They also show how the topic *multicultural curricula and instruction* tends to dominate the scholarship but remains “at the stage of calling for action” (Liu et al., 2020: 290). Like Wang (2018) they also note a lack of empirical research on Minzu teacher education. All in all, they confirm that the discourse of national unity and integration is omnipresent in Chinese Minzu education.

In 2021, Wang (2021) published a research paper about the inclusion of Minzu cultural content in school practices by means of e.g., bilingual education and cultural courses and activities (see Zhang and Chen, 2014 as an example of a previous study on the same topic). Based on data collected in two Minzu areas with representatives of different Minzu groups, the author notes what he refers to as “superficial modalities” in the way Minzu cultural content is integrated in schools or their mere additive nature (e.g., Minzu issues being proposed as extracurricular activities and “performed” solely during traditional festivals). He also notes that “Underlying cultural attitudes, values and beliefs are not reflected in school practices” (Wang, 2021: 122). Teachers appear to be interested in promoting Minzu cultures but, for instance, the fact that the inclusion of Minzu knowledges in their teaching does not play a role in their yearly appraisal seems to not motivate them to include them systematically (Wang, 2021). Wang explains (2021) this lack of inclusion by the centralized nature of educational governance and, especially, by means of the concept of “Chinese internal orientalism”, whereby Minzu cultures are represented in static ways. In his conclusions, Wang (2021: 123), influenced by American (critical) multicultural education, argues that:

At present, the restrictive and highly centralised curriculum framework makes it rather difficult for teachers, whatever their own ethnicity [i.e., Minzu], to break through the curriculum structure and use advanced approaches to multicultural education, such as transformative and social actions which would encourage students to think about concepts, issues and events from the perspective of diverse ethnic groups, and empower them to make decisions on critical social issues.

What the reviews we have consulted in Minzu education (and our knowledge of the literature) show is a lack of discussions around knowledges from the 56 Minzu groups for education, especially beyond “Western” critiques of multiculturalism.

There is another strand of research which could be of interest to interrogate Minzu “indigenous” knowledges: *Chinese multilingual education* (see e.g., Rehamo and Harrell, 2017). This other broad field of research covers national, Minzu and foreign languages and

often includes discussions of epistemic diversity. In their (2021) edited volume Adamson and Feng note threats to the sustainability of weak languages and dialects in China where over 100 languages are spoken on top of Chinese, with many Minzu groups having their own languages (e.g., Mongolian, Uyghur, Yi, Zhuang). In one of the chapters, Wang et al. (2021) write about what they call “Local Knowledge Instruction” (LKI) for Minzu learners in Yunnan, inspired by the American concept of *Culturally Responsive Teaching*. LKI is described as daily life and native literacy and numeracy knowledge linked up with school literacy development (Wang et al., 2021: 171). This appears to be the closest to the idea of indigenous knowledges. In their chapter, Wang et al. (2021) describe an initiative dating back to 2009 whereby Minzu University of China (a university focusing on Minzu studies located in Beijing) and some NGOs published two LKI textbooks for primary schools. Their evaluation of the initiative reports teachers’ mixed feelings about introducing such knowledge in Yunnan. As such local Minzu teachers felt that the Minzu knowledge found in the textbooks was too localized, which could create tensions among representatives of the Minzu in other parts of the country. Wang et al. (2021) also note that the fact that there is no pre- and in-service teacher training around LKI represents a major inconvenient. In general, reading the chapter, one is not too clear about what LKI includes, who decides what to include and how to deal with the potential epistemological clashes between (and among) local knowledges and traditions and school knowledge. All these essential questions remain at the center of interrogating indigenous knowledges in relation to Minzu education.

How to identify Minzu knowledge?

In this section, we take a closer look at *if* and *how* Chinese teachers of Mongolian Minzu working in the region of Inner Mongolia both justify and engage with the use of Minzu knowledge in STEM education.

In a 2022 paper, Xu discusses the idea of epistemic diversity and cross-cultural comparative research. In the paper she problematizes and criticizes the very term of epistemic diversity and especially what she refers to as “long-standing normative appeals for epistemic diversity, decolonization, democratization and justice” (Xu, 2022: 37). She notes that questions such as “who has the right to create and own knowledge, and to be respected, heard, seen in their capacity as a knower?” (Xu, 2022: 37) are being addressed rightly today, through different perspectives such as decolonization and postcolonialism. However, she also maintains that the answers provided to the aforementioned questions are often very much framed within Western critical discourses, which still evacuate alternative voices. Xu maintains that “academic voices from the non-dominating spaces are often again marginalized, ignored, appropriated or excluded, demonstrating yet another layer of epistemic injustice” (2022: 38). For research and education around indigenous knowledge, these issues are very much relevant: *how to get out of the vicious circle of “still” making use of westernized and dominant ideologies? Who decides what knowledge is and how it should be imparted? And who has the right to judge if imparted knowledges are valuable, “essentialistic” and/or “superficial”* (see Wang, 2018)?

Although we the authors work constantly with people of other Chinese Minzu groups, none of us belongs to a Minzu “minority” group. Fred is from Europe and Mei is a member of the Han Minzu group. This does not make us feel too comfortable “judging” e.g., Mongolian Minzu teachers for their use (or not) of Minzu knowledges. Therefore, for us, identifying Minzu knowledges in teachers’ practices in the next section will not be about *evaluating* what they do (or not) but about providing a first snapshot of the topics of indigeneity, Minzu and knowledges in Chinese education. We always need to remember that teachers are educated and trained in specific ways, that they have their own beliefs and attitudes toward political issues such as the inclusion of specific knowledge and that they may not want to reveal their “inner” thoughts about the topic of Minzu knowledges during a research interview. Finally, since the data we collected was based on interviews (rather than e.g., observations), we need to remember that what people say during interviews may not always correspond to what they do in complex teaching situations.

Deciding upon how to identify Minzu knowledges in the research interviews at our disposal required careful consideration. After consulting the literature, we have decided to make us of Bruchac’s (2014) paper entitled “Indigenous Knowledge and Traditional Knowledge”, which appears to be a good starting point. Anchored within the field of global archeology, the paper defines traditional indigenous knowledge as follows (2014: 3816):

a network of knowledges, beliefs, and traditions intended to preserve, communicate, and contextualize Indigenous relationships with culture and landscape over time. One might distinguish “knowledge” as factual data, “belief” as religious concepts, and “tradition” as practice, but these terms are often used imprecisely and interchangeably to describe Indigenous epistemologies.

A series of keywords found in the definition can help us adopt an open approach to Minzu knowledges when combing through our data: *knowledges* (understood as “factual data”), *beliefs* (“religious concepts”, we add worldviews here) and *traditions* (“practice”). These three elements are used as “gauges” to examine our data in what follows. Bruchac (2014: 3817) also provides a concrete list of such knowledges:

oral narratives that recount human histories; cosmological observations and modes of reckoning time; symbolic and decorative modes of communication; techniques for planting and harvesting; hunting and gathering skills; specialized understandings of local ecosystems; and the manufacture of specialized tools and technologies (e.g., flint-knapping, hide tanning, pottery-making, and concocting medicinal remedies).

Traditional ecological knowledge or “Native science” (Cajete, 2000) is also presented as an important element to take into account by the author (Bruchac, 2014). These include: “philosophies and practical measures that are intended to preserve cultural heritage and protect ancestral landscapes and lifeways” (Bruchac, 2014: 3818). Finally, the importance of oral traditions (e.g., mythical stories) is also emphasized by Bruchac (2014: 3820):

Indigenous oral traditions often contain insightful explanations that focus on details: origin stories referencing natural and constructed features of the landscape; descriptions of the beings that inhabit this landscape; articulations of the reciprocal relations among these beings; and traditional beliefs that guide human interactions with place.

Bruchac (2014: 3821) reminds us that indigenous knowledges are often viewed with suspicion both by common people and scholars, especially when they are contrasted to “scientific knowledge”. However, she also notes that indigeneity can enhance scientific knowledges as many anthropological and indigenous scholars have demonstrated (Bruchac, 2014: 3821).

Mongolian STEM teachers reflecting on the use of Minzu knowledges in their teaching

In the rest of the chapter, we focus on a case study based on interview data with 9 teachers collected in different schools in the Inner Mongolia Autonomous Region (Northern China, on the border to Mongolia and Russia). The region has approximately 25 million inhabitants for a total area of about 1.1 million km². The vast majority of the population is constituted by the Han Minzu. The second largest Minzu group is that of the Mongols (about 17%). Other Minzu groups living in the region include e.g., Hui people, Manchus and Koreans. Some Mongols are followers of Tibetan Buddhism while e.g., some members of the Hui group follow Islam (Sude et al., 2020). According to the 2020 census, 67.48% of the population lives in urban areas while 32.52% in rural areas (National Bureau of Statistics of China, 2021). Worlddata.info (2022) claims that 5.64 million people speak Mongolian in China. Many speakers of the language are also located in provinces other than Inner Mongolia such as Qinghai, Xinjiang and Gansu. Mongolian has its own writing system adapted from an old Uyghur script. Although there were rumors in the global media in 2021 about the Mongolian language being “phased out” from education in Inner Mongolia (e.g., in the Xilingol League in the central region), Mongolian schools do teach subjects in Mongolian and offer bilingual education too. Chinese language and literature (the common language of China), Ethics and Law, and History, are taught in Chinese. Students can choose to go to Minzu schools where the Mongolian language is the medium of instruction and Chinese a subject or a Chinese-medium school where Chinese is the language of instruction and their Minzu language is taught as a subject. We collected the data from both kinds of schools (T: 5) in the city of Erdos (鄂尔多斯), a prefecture-level city located in the southwest of Inner Mongolia. Together with Hohhot and Baotou, Ordos constitute the economic triangle of the region. A cluster of different cities, Erdos has a population of about 2 million people (Statista, 2022).

In what follows we listen to 9 teachers of Science Technology Engineering and Mathematics (STEM). 7 of the teachers were of Mongolian Minzu, who all spoke Mongolian and Chinese and 2 Han teachers who also spoke both languages. 5 of the teachers were teaching in a Minzu school (Mongolian as the dominant language and Chinese as a subject) and 4 in Chinese-medium schools. All the schools were 初中 (middle school), i.e., the first three years of secondary education in China. Some teachers had just one year of experience teaching STEM while others 15. Finally, all the teachers were working with groups of both Han and Mongolian Minzu students. Table 1 provides basic information about the teachers.

The interviews were done in Chinese and Mongolian, translated and negotiated in English between us. Like other parts of the world, STEM is an important subject in China and according to Li (2018: 2): “Efforts are being made in China to stimulate student inquiry, innovation, and critical thinking in and through STEM education”. Many scholars have worked on STEM education worldwide within the subfields of e.g., culturally responsive STEM or Multicultural STEM education, arguing e.g., that it can support both teachers and students in revising their beliefs about e.g., mathematics being “neutral”; testing out culturally responsive instructional

Table 1 Basic information about the STEM teachers.

<i>Teacher</i>	<i>School subject</i>	<i>Minzu</i>	<i>Type of school</i>
Teacher 1	Technology	Mongolian	Mongolian school
Teacher 2	Science	Mongolian	Mongolian school
Teacher 3	Chemistry	Han	Mongolian school
Teacher 4	Technology	Mongolian	Chinese-medium school
Teacher 5	Science	Mongolian	Mongolian school
Teacher 6	Chemistry	Mongolian	Chinese-medium school
Teacher 7	Maths	Han	Mongolian school
Teacher 8	Science	Han	Chinese-medium school
Teacher 9	Engineering	Mongolian	Chinese-medium school

strategies and being opened to students’ thinking and problem solving (Ukpokodu, 2011). By including indigenous knowledges in STEM, one might also promote more interest in them. In what follows we are interested in seeing if and how Mongolian Minzu knowledge is included in STEM education in the schools under review.

Let us start with some comments on training and education. Officially, STEM education with Minzu characteristics is not discussed at school or in teacher education and training. All the teachers agree that there is no formal teacher education and training related to Minzu issues for STEM. When she details her preservice training, teacher 3 provides information about how she has learned to use e.g., PPTs for showing “real examples from life”. When asked how much she took Minzu examples into account, she replied that she did not. Teacher 2 also explains that he has taken a lot of extra training courses during his years as a STEM teacher. None of these courses were specifically targeted at Minzu knowledges but he argues that the imparted knowledge “is applicable to all Minzu groups” and that everyone can learn from “the excellent culture”, meaning from general international STEM knowledge. The phrase “excellent culture” (优秀的文化, Yōuxiù de wénhuà) to refer to “superior” and “more advanced” knowledge is commonly used in Chinese.

Teacher 1, who is herself Mongolian, also confirms that she received no specific training since “we teach all students the same way”. However, further in the interview, she mentions that her Mongolian family background has urged her to be interested in extracurricular activities such as physical education and technology and to learn more by herself. She claims for example that she has also taught music, painting, science and technology, and physical education in primary school. Contrasting Han and Mongolian families, she argues:

Excerpt 1

Many Han parents do not support students to participate in extracurricular activities. They support them to participate in activities that are beneficial to them, such as piano, English, etc. But they don’t support students to participate in subjects that they find useless such as science and technology and sports. But our Mongolian parents never do like that. As long as students like it, parents will support them. They believe that students should be widely involved in all kinds of knowledge and develop in an all-round way. We grew up with such an educational concept.

Although this statement might appear somewhat essentialist (Han families vs. Mongolian families), we are here within *beliefs* about education rather than *Minzu knowledges*. At this stage we should note that contrasts between Han and Mongolian, teachers, parents and students are omnipresent in the interviews, with Mongolian students being systematically constructed as “freer”, “more gifted for craft, singing and sports” and “less hardworking”/“passive”. In terms of STEM the teachers seem to agree that Mongolian students are more curious, better at experiments and manipulations, and eager to take part in activities such as competitions. Although some teachers might state that there is no difference between them, at different moments in the interviews, they often contradict themselves. For example, teacher 4 starts the interview by claiming that there are no differences between Han and Mongolian students and teachers. However, later on in the interview, when asked to compare them, he notes that, although Mongolian students are very much interested in STEM, their inventions are not new as such and that their lack of interest in innovations from other Minzu groups creates a gap in their STEM knowledge and creativity. About Mongolian teachers—as a reminder, the interviewee is himself a Mongolian Minzu—he argues that they tend to be too proud of “their own Minzu things” and that they “should pay more attention to other Minzu groups”. This argument was uttered by two other Mongolian teachers in the data, drawing systematically the same conclusion that one should pay attention to this issue in the future. To finish on the topic of comparing Han and Mongolian Minzu group members, we note that teacher 5 is the only one to divide Mongolian students into subgroups, on the basis of geography: “For example, we say that our children in the west are not working very hard. It may be because their families are very wealthy. Children in the northeast side are more hardworking.”

Finally, about training, a Han teacher working in a Mongolian school (teacher 7) describes how she was trained when she moved to Inner Mongolia:

Excerpt 2

When we came to Inner Mongolia, we took a special training, where they gave us some precautions. In fact, I think that in this school, many Mongolians have become more sinicized, and many living habits are not much different from those of the Han people. I think we should pay attention to it a little bit. But there are not as many taboos as some ethnic groups like the Hui, so it’s okay to be in a school with Mongolians.

This is the only teacher who mentions having received this kind of specific training, where she was given “some precautions” about working with Mongolians. Although she does not give much information about the content, at the end of the excerpt the keyword of “taboos” seems to indicate that this “special training” was about “do’s and don’ts” and cultural aspects of the Mongolian Minzu—see the use of “living habits” in the excerpt. The argument that Mongolians have become more “sinicized”—meaning more “similar” to the Han majority Minzu—is recurrent in some research on Chinese Minzu (e.g., Yang, 2017), however, what *sinicized* means considering the diversity of the Han Minzu too, is not clear-cut (on a critical review of the idea of “sinicization” see Cheng,

2021; on the Han “China’s diverse majority”, see [Joniak-Luthi, 2015](#)). Here again, the training did not seem to be concerned about including Minzu knowledges but more about beliefs and (maybe) traditions ([Bruchac, 2014](#)).

Before looking more specifically into Minzu knowledges that might be introduced into STEM education in the schools under review, let us say a few words about language issues. As said earlier, some teachers work in Mongolian-language schools with some Chinese used for specific courses and others in Chinese-medium school, with Mongolian taught as a subject. In the Chinese-medium school, where both Han and Mongolian teachers work, the majority language is Chinese and teachers have a duty to use the language in school (except in Mongolian language lessons). Teacher 2 explains:

Excerpt 3

If I teach in Mongolian in class, I would violate the education law, but it can be done after class. If some Mongolian students ask me questions after class, I will interact with them in Mongolian.

Both the Han and Mongolian teachers who work in the schools under review agree that Mongolian teachers are usually closer to Mongolian students. Teacher 7 maintains that “students will have a sense of identity in terms of culture and language, and this sense of identity may make them interested in this teacher and thus in this course.” In the interviews, the teachers who work at Mongolian schools all agree that the students should be taught and spoken to in Mongolian since some of them, especially from the pastoral areas, are not proficient enough in Chinese. However, some teachers argue that STEM should occur in Chinese because “some knowledge cannot be understood by students in Chinese” (Teacher 1). Teacher 2 is the only one who believes that Mongolian and Chinese should be both used in teaching, as “a complement to each other”. He gives the example of scientific and technological words which do not exist in Mongolian such as *tractor*, *airplane* or even the verb *to dissolve*, maintaining that the use of Chinese and/or English can support learning.

The following paragraphs focus on (Mongolian) Minzu knowledge in STEM education. When asked directly to mention how Minzu knowledges are included in the lessons, all teachers except one, provide some examples. Teacher 8, a Han Minzu science teacher working in a Chinese-medium school, explains:

Excerpt 4

If the topic at hand is close to Mongolian culture, I will adapt different methods, but the science subject is more theoretical and rational. Science just has one truth, so we don’t have any special ways, there is no difference between Minzu groups.

The argument of science being “neutral”, and thus that no other knowledge is required in class, has been noted in most research on e.g., culturally responsive STEM education around the world (e.g., [Ukpokodu, 2011](#): 48).

Like the other teachers, Teacher 7 seems eager to include Minzu aspects in their teaching but admits that their lack of knowledge prevents them from doing so. The only concrete example that they put forward is a reference to the largest open-pit coal mine in Inner Mongolia—which they admit contains no “Minzu aspect”. At the end of the interview, the same teacher replies to a final question about recommendations they would make for Minzu STEM education:

Excerpt 5

First, we have to learn Mongolian culture, whether it is language or some traditional customs. If we have such a traditional cultural heritage, we will have better communication with students, and they will have a sense of identity. A sense of identity may make the relationship between teachers and students more cordial and make them identify more with the teacher; second, in a class where Mongolian and Han students teach together, it’s best not to individually propose what should be done to Mongolian students. Let everyone blend together and don’t deliberately make this distinction. Because if there are very few Mongolian students in a class, it may make them bear some different perspectives, so I don’t think it is necessary to deliberately emphasize these differences.

Teacher 7 starts by insisting on the importance for a teacher to know the Mongolian language and “traditional cultural heritage”—without giving details, except the generic “traditional customs”—to stimulate Mongolian Minzu students and to create “bonds” with them. However, when she mentions both Han and Mongolian students, in order not to create some sort of disadvantage, she suggests treating them the same way (“let everyone blend together”) and thus put aside e.g., Mongolian culture and language (see similar results in [Wang, 2021](#)).

In what follows, based on [Bruchac’s \(2014\)](#) categories of *knowledges*, *beliefs* and *traditions*, we introduce some of the examples presented by the interviewees. Reading through what they say and the entire interviews (which focused on the very topic of including Minzu knowledges in STEM education), one notices that these could often appear to be “add-ons”, “improvised” and on the verge of stereotyping at times, and that there is no systematicity in their inclusion. Besides, we note that “dividing” the examples into the three categories was not always easy as some examples seemed to fit into different categories.

We start with knowledges, which is understood here as facts, theories but also consciousness and awareness derived from the Mongolian Minzu group. Three teachers provided the following examples:

Knowledge relating to living experiences (pastoral areas)

For example, for measurement in mathematics, especially for the children living in pastoral areas, the issue of distance, they can understand more easily if I mention that a few kilometres equal to a certain number of meters. Because in their real lives, they often have to do something a few kilometres away, they have already grasped this in practice (teacher 4).

Knowledge about nutrition (Huoliao porridge)

In terms of food, have you ever eaten Huoliao food (Mongolian porridge)? The ingredients are beef or mutton, rice, water and salt. For Mongolian people, this meal is a common home cooked meal. But I say to the students: in fact, relevant experts believe that this meal is the best meal one can get. Then the students ask *why? Isn't this the most common meal we eat every day?* I ask them in return: *why is your body so strong?* Although this is a kind of Mongolian food, its nutritional value is very high. The human body needs sugar, fat, protein, inorganic salts, vitamins and water, which are all included in this special porridge, so it is the best food from the perspective of nutrition (teacher 2).

Knowledge about place and space

For example, when teaching Han Minzu students, most teachers will use Tiananmen Square [in Beijing, opposite the Forbidden City] for discussing distance. When they talk about the size of 100 square meters, teachers will use Tiananmen Square or the school playground as an example. But the Mongolian teachers don't use these examples, they might refer to how big a sheep pen is and how big a cattle pen is. First, I thought in my lessons, as a Chinese, we should all know Tiananmen Square, but children living in pastoral areas have never been there (teacher 6).

For Bruchac (2014) beliefs refer mostly to “religion”. However, here we understand the word to mean principles, values, representations, philosophies, and views. Although examples from the two other categories also seem to fit in this one, we have identified two teachers making specific references to Mongolian beliefs in the examples they give:

Belief about water and ecological frugality

Let me think about it ... Mongolian ... Um ... About the Mongols ... (Long pause) Well, it could be a frugal aspect of Mongolian culture. Because we have water in the fourth chapter of the textbook, I just tell them that this is about frugality, we don't waste water. For Mongolians water is an essential part of their culture (teacher 2).

Belief about animals (the horse)

This is a horse's belly bag, which is put on the saddle. Ordinary teachers would simply perfunctorily explain that this horse's belly bag is made of a horse mane. When I explain to the students, I would say: This is the belly bag of a horse. It was made of a horse mane. I would ask: *Why did ancient people use horse hair to make this?* The students have a lot of ideas on this issue. I will then explain to them that the Mongols are nomadic people, so they have great feelings for horses. If you use leather or other things to make horse harness, it is not good for the horse's health. If you make clothes for the horse with the things that grow on the horse, it will do little or no harm to the horse. This is a manifestation of life skills (teacher 5).

Traditions is the category where most examples were identified in the interviews. They correspond to practices, interests and artifacts of the Mongolian Minzu:

Traditions related to manual work

I'd like to add some new contents in my teaching, such as enhancing handicraft. Because I pay attention to handwork, I found that Minzu students have a strong practical ability. They can make desks, chairs and daily necessities by themselves. They can also create some new things by hand, such as making some things with plenty of pencils. Mongolian tools and hand-made equipment are very developed (teacher 1).

Traditions related to architecture

Recently, we have specially organized training courses for teachers in this area. There is also laser cutting. Our division is more interested in laser cutting, so we developed and designed all the necessary components of the yurt [Mongolian tent] on the computer, and then cut it out to make something like a product. It can be sold, and students can also experience assembling this yurt for free. Yurts and other Mongolian elements are also decorated (teacher 9, Mongolian, engineering, Chinese-medium school).

Traditions related to music

We have a special class, where the students work on and design Mongolian musical instruments such as the matouqin [a two-stringed instrument with a trapezoidal body and handle shaped like a horse head] (teacher 3).

Behaviors

In two interviews, both a Han and a Mongolian teacher (teachers 8 and 3) share their surprise about having witnessed some Mongolian students kowtow to them.

Discussion and conclusion

To our knowledge this is the first attempt to link global questions of indigenous knowledges in education and the specific context of Chinese Minzu. We started by interrogating the words used in Chinese to refer to the (polysemic) notion of indigeneity in comparison to English, and noted that the more direct equivalent word is not used within China to discuss Chinese indigenous diversity. Other words were critically reviewed based on previous research and the notion of Minzu, used politically, in education and research in Mainland China, was introduced as a “companion” to issues of indigeneity in China. Reviewing some studies about how it has been implemented, the problems that both researchers and educators face when working on Minzu (e.g., an overreliance on “Western” multicultural education paradigms), we reflected on what identifying Minzu knowledges in Chinese education, especially in diverse Minzu areas, would mean. We explained that we felt uncomfortable about “judging” e.g., teachers about the kind of Minzu knowledges that they make use of. Using the “simple” model of indigenous knowledges proposed by Bruchac (2014), from the field of archeology, we combed through interview data with different kinds of teachers of STEM from Inner Mongolia.

Our study confirms first and foremost Wang’s (2021) study that there is a lack of formal training for teachers to include Minzu knowledges and that the kind of education and training that teachers seem to receive has to do with “general international knowledge” about STEM or with culturalist information about Mongolian Minzu students. What the analysis of the interviews reveals is that teachers do include some Minzu knowledges in their lessons, as well as aspects of Minzu beliefs and traditions—the latter being the most common one in the examples given by the teachers. This inclusion is clearly not systematic and one can see that most teachers are “juggling” between the key Chinese terms of “unity” (i.e., togetherness) and “diversity” in discussing if and how they include Minzu knowledges. In the interviews, some of the teachers maintain that they do not wish to disadvantage any student by including knowledges and/or multilingual elements while arguing that for some students (e.g., Mongolian students from pastoral areas who do not have proficiency in Chinese) such practices are highly recommended. Looking at the examples again, one can feel that the elements contained in the categories of knowledges and beliefs are potentially the most interesting ones since they relate what students learn to principles, values, representations, views and philosophies derived directly from their Minzu group. These seem to go beyond the “content integration” described by Wang (2021).

The discussions around indigeneity, Minzu, and epistemic diversity presented in this article leave us with (at least) two important sets of questions:

- Inner Mongolia is a complex ensemble of people from several Minzu groups (Han, Mongolian but also Hui, Manchu and Korean) who attend all kinds of schools (e.g., Mongolian and Chinese-medium), often together. Who decides then what Minzu *knowledges, beliefs and traditions* should be included and for whom? If the focus is only on Mongolian Minzu knowledges, is there a risk for both teachers and students to close themselves up in one “knowledgescape”? One could also ask the following questions: Should Minzu knowledges be introduced separately and/or concurrently? Should they be problematized through the concepts of *melange* or *mixing* (Pieterse, 1996) since Chinese Minzu groups have influenced each other throughout the centuries, instead of presenting them as separate blocks? For example, the Mongolian Minzu group has been highly influenced by both Tibetan and Uighur Minzu traditions and beliefs. For teachers this all relates to the important question of how to maintain the central ideology of *unity in diversity* while opening up students’ Minzu “knowledgescape”. Since teachers do not receive training or preparation on these issues, we can only suggest that individual teachers reflect on these questions for themselves and with others if possible. We also believe that these questions are relevant for many other contexts in the world.
- The question of languages is central to the case of Inner Mongolia since the Mongolian Minzu has its own language—like many other Minzu groups. Many examples found in the data refer to a subgroup from the Mongolian Minzu: students from pastoral (grassland) areas. These students are often described as having specific knowledges related to their upbringing and a lack of skills in the common Chinese language, using Mongolian as their main (and often only) language. In previous (international) research on Minzu education, the issue of language use in and outside education is rarely addressed in relation to Minzu knowledges. How could one link them up more systematically? In other words, how could language(s) provide more in-depth access to knowledges, beliefs and traditions? How could e.g., discussions around the translation of specific terms or etymologies deepen our understanding of indigenous knowledges? We also feel that these questions are central to global approaches to indigeneity in education.

Introduction

The story I would like to tell extends conversations on the intricacies of a pedagogy enacted by the agency of Kānaka 'Ōiwi¹ and grounded in 'āina, called 'āina-based education. Physically, 'āina includes the land, earth, and all that nourishes life. Holistically, "The 'āina sustains our identity, continuity, and well-being as a people. It embodies the tangible and intangible values of our culture that have developed and evolved over generations of experiences of our ancestors" (Kikiloi, 2010, p. 75). Kanaka educator and cultural practitioner, Kamoā'e Walk adds that the 'āina not only *sustains* our identity, it *is* our identity, means for continuity, and well-being as a people (Personal Communication, K. Walk, May 2021). As the Indigenous people of Hawai'i, our genealogies teach us that we descend from the primordial forces that birthed the islands we call home, documented in the many mele ko'ihonua (cosmogonic accounts) that inform Kānaka 'Ōiwi in the present day. In the 'ōlelo no'ēau (proverb) he ali'i ka 'āina, he kauwā ke kanaka (the land is a chief, man is a servant) (Pukui, 1983), the order and relationship that humanity and the earth coexist, is revealed .

Opening with a story

The first kalo (*colocasia esculenta*) harvest from my family's garden was very special. On a cool morning in Waipahū on the island of O'ahu, my father and I harvested the first row of kalo we planted in the red soil of Waipahū about eight months prior. We cut off the kalo corm, cut off the lū'au (leaves), and saved the huli (middle of the plant; stalk) to replant. We steamed the corm until the skin started to peel, scraped the skin off until it was clean, and I pounded it with a wooden board and stone until it was 'ūlika (soft and gummy). I carefully added water and mixed until it was the smooth consistency we call poi. My family ate the poi with the cooked lū'au and it physically and spiritually nourished us that day. This was the first time we ate kalo that we planted, cared for, and prepared with our own hands. My family had previously only eaten poi out of a plastic bag purchased from the grocery store. Here in Hawai'i, the price of poi ranges anywhere from five to twelve dollars per pound due to the rising cost of land and the meticulous process of growing and processing—making it inaccessible to many families whose ancestors may have eaten it daily.

¹Kānaka 'Ōiwi, Kānaka (plural), Kanaka (singular), Hawaiian are terms used to describe the indigenous people of Hawai'i. Kanaka and 'Ōiwi are also used as adjectives. When spelled kānaka (plural), this refers to all of humanity.

I share this mo’olelo (story, history, account) to begin this paper because as Kanaka ‘Ōiwi, kalo is my ancestor. But like many Kānaka ‘Ōiwi today, I did not grow up knowing the genealogies of my ancestors due to settler traditions of Western domination, assimilation, and hegemony. It was not until later in my life as young adult that I learned the genealogy of Papa and Wakea—one of many mele ko’ihonua that “identify and connect Kānaka to our kūpuna (ancestors; elders) and our ancestral homelands” (Oliveira, 2014, p. 24). *Malo (1903/1951)* provides this account of Papa and Wakea:

O Wakea noho ia Papa-hanau-moku, Hanau Hawaii, he moku, Hanau Maui, he moku. Hoi hou o Wakea noho ia Hoo-hoku-ka-lani. Hanau Molokai he moku, Hanau o Lanai ka ula, he moku. Lili-opu-punalua o Papa ia	Wakea lived with Papa, begetter of islands Begotten was Hawaii, an island Begotten was Maui, an island. Wakea made a new departure and Lived with Hoo-hoku-ka-lani. Begotten was Molokai, an island, Begotten was red Lanai, an island. The womb of Papa became jealous Hoo-hoku-ka-lani. Hoo-hoku-ka-lani. At its partnership with
Hoi hou o Papa noho ia Wakea. Hanau o Oahu, he moku, Hanau o Kauai, he moku, Hanau o Niihau, he moku, He ula a o Kahoolawe.	Papa returned and lived with Wakea. Begotten was Oahu, an island, Begotten was Kauai, an island, Begotten was Niihau, an island, A red rock was Kahoolawe (p. 243).

Following the creation of the islands, Wākea and Ho’ohōkūkalani’s firstborn child was of premature birth named Hāloa-naka. Hāloa-naka was buried in the earth and from the body grew the first kalo plant. The leaf was named lau-kapa-lili and the stem was known as Hāloa. Soon after, another child was born named Hāloa. Hāloanakalaukapalili is a common name that refers to the first kalo plant and Hāloa is known to be the first Hawaiian chief and primordial ancestor to all Kānaka ‘Ōiwi. While different accounts of Hāloa are told today, we are taught that this mo’olelo is an account of order and place in the universe. Older than humanity is Hāloa, the first Hawaiian chief. Older than Hāloa is Hāloanakalaukapalili, the first kalo plant and staple food of the Hawaiian people. Older than kalo are the islands, the land that Hāloanakalaukapalili grew from, and older than the islands are the elemental forces that created them. This genealogy reminds me of my place in the world. As a young adult, it also reminded me and my family of a way to connect with ‘āina in pono relationship.

Centering Kanaka ‘Ōiwi perspectives of place and decolonizing place-based education

As trending educational movements such as STEM and sustainability education take “place-based” approaches to address issues of the 21st century, it is critical that Indigenous Peoples center and advance the knowledge systems that have connected people and the land as life for generations. The limitations of place-based education in Indigenous communities are widely researched (Calderón, 2014; Corbett, 2020; Saffery, 2019; Seawright, 2014; Webber, 2017). Corbett (2020) posits that some versions of place-based education “might be described as place-limited education in the sense that they appear to begin and end in tightly bounded space” (p. 280). Extending from this idea, Calderón (2014) explains the importance of centering the relationship between land and settler colonialism:

Such a positioning is important, particularly from an Indigenous perspective, because it makes ideologies and structures of settler colonialism explicit. It demands that in articulating place-based models for forming relationships with place, the legal landscapes (Delaney, 1998) of settler colonialism be delineated and deconstructed (p. 26).

Without this delineation, place-based education may perpetuate settler notions of place, exemplified in the Western concept of “sense of place”, often ignorant of Indigenous processes of relating to land, time, and space (Brookfield, 1973; Fox and Cumberland, 1962; Lilomaiva-Doktor, 2020). Grande (2015) explains, “The centrality of place in the Indigenous thought-world is explicitly conveyed through tradition and language and implicitly through the relationship between human beings and the rest of nature” (p. 240). ‘Āina education (Saffery, 2019), aloha ‘āina-placed education (Oliveira, 2017), and for this paper I utilize the widely referenced term ‘āina-based education, seek to connect learners in appropriate ways to how Kānaka ‘Ōiwi relate to ‘āina through familial, spiritual relationship and kuleana (responsibility, privilege, obligation).

Revisiting the term “'Āina-based”

It is important to note that the term “'āina-based education” is contentious. Oliveira (2017) claims that “'āina-based” merely Hawaiianizes “place-based” in reference to place-based pedagogy, as “place” is simply translated to “'āina.” Instead, she uses the term “aloha 'āina-placed education” and emphasizes that aloha 'āina-placed education is:

... more than simply learning that occurs outside of the classroom. Aloha 'āina-placed education is a recognition that Kanaka are genealogically related to the 'āina and the 'āina is our ancestor. The 'āina is not only the source of our physical nourishment, but it also feeds us spiritually and mentally. Aloha 'āina-placed education reinforces the notion that Kanaka have a birthright to reside on the 'āina and by virtue of this birthright we also have a kuleana (responsibility, burden) to care for and protect the 'āina (Oliveira, 2017, p. 6).

I agree with Oliveira that the term 'āina-based education has become mainstream. Her justification that more emphasis is needed to articulate genealogical relationship and kuleana to 'āina resonates with me. Yet it is unclear where the term “'āina-based” originates or whether or not the term was intended to be a Hawaiianized version of “place-based education.” This uncertainty highlights the need to clarify the presence of Hawaiian terms and concepts in educational frameworks. Claiming the use of the term “'āina-based education” puts Kānaka 'Ōiwi in the place of power to define what 'āina-based education truly requires, especially as academic institutions find value in “place-based” educational approaches and begin to institutionalize 'āina-based pedagogies.

Research studies that detail the nature and impact of 'āina-based education have only emerged in the past two decades, whereas the foundational principles that undergird 'āina-based education are firmly rooted in ancestral Hawaiian epistemologies. The Hawaiian-focused Charter School Ko'olau 'Āina-based Hui defines 'āina-based education as:

Learning experiences that allow learners to create authentic, reciprocal relationships with the land, people, and resources of a specific community. This becomes an integral part of the learner's identity and a catalyst for a personal commitment to the health and well-being of that community. It is situated in learning that honors the past, present and future in order to ensure the sustainability and productivity of all forms of life. More specifically, 'āina-based education embodies the wisdom of the 'ōlelo no'ēau: 'O ka hā o ka 'āina, ke ola o ka po'e (The health of the land is the health of the people) (Kanuiakapono, 2020, para. 3).

'Āina-based learning approaches include dynamic and interdisciplinary processes of learning and teaching that hail from the natural landscapes and oceanscapes of Hawai'i's environment. These processes, which emphasize reciprocal interconnected relationships between Kānaka 'Ōiwi and the 'āina, draw upon place-specific intergenerational knowledge systems, language, and customary practices to frame curricula for all learners (Maunakea et al., 2020, 2022). This research explores *how* and *to what end* 'āina-based learning is being offered across diverse educational settings. I draw from Kānaka 'Ōiwi and Indigenous methodologies (Oliveira and Wright, 2016; Smith, 2021) to weave the voices of Kānaka 'Ōiwi educators, researchers, and cultural practitioners into a collective framework for 'āina-based education—further contributing to Kānaka 'Ōiwi directions for 'āina-based educational models and “place-based” approaches to learning.

Addressing settler traditions of place

'Āina-based education has been in large part operationalized in resistance to settler colonialism (Goodyear-Ka'ōpua, 2013; Vaughan, 2018). Seawright (2014) employs the term “settler traditions of place” to describe modes of domination built on “racialized, anthropocentric, and capitalistic understandings of place” (p. 554) that originate in Western epistemological foundations. Domination manifests itself as settler colonialism, white supremacy, anthropocentrism, heteropatriarchy, and other forms. Seawright (2014) explains, “healthy, sustainable, and reciprocal relationships to the social geography we are emplaced in have been bastardized, corrupted, and perverted by the same systems that let capital, competition, and private property define life” (p. 571). In Hawai'i, the commodification of the natural landscape due to development, industrialized agriculture, militarization, over-tourism, and urbanization has amounted to unforeseen levels of environmental degradation and separation of Kānaka 'Ōiwi from 'āina (Osorio, 2014). Considering Hawai'i's unique political status as a sovereign nation occupied by the United States of America government (Silva, 2004) and the history of American indoctrination on the education system (Kaomea, 2000; Benham and Heck, 1998), a critical gaze into place-based education literature is fitting.

The need to claim and advance Indigenous peoples' processes of learning and teaching

Once a space has been cleared of native culture and attachment, its voice becomes that of the detached scientist and the citizen-of-the-world environmentalist (Beamer, 2014, p. 41).

Kanaka ‘Ōiwi and Indigenous scholars assert the need to claim and advance Indigenous ways of knowing and being in research, language, schooling, and systems to make positive differences in their lives (ho‘omanawanui, 2008; Kana‘iaupuni et al., 2017; Maaka, 2004; Smith, 2021). Culturally sustaining and revitalizing pedagogies such as those that center land-based literacies provide counter-narratives to settler legacies in education (McCarty and Lee, 2014; Saffery, 2016). These learning approaches have been described as land education (Tuck et al., 2014); Indigenous land-based education (Wildcat et al., 2014); and Indigenous place-based education (Cajete, 1994; Kawagley and Barnhardt, 1999; Penetito, 2009). Land education as discussed by Tuck et al. (2014) has the power to

Remind people to place Indigenous understandings of land and life at the center of environmental issues and other (educational) issues; provide an explicit critique and rendering of settler colonialism, treaties, and sovereignty; invite and inspire acts of refusal, reclamation, and reimagination; and theorize pathways to living as separate sovereignties on shared territory (Simpson, 2013) (p. 19).

Similarly, Indigenous land-based education operates on the premise that if colonization is about dispossessing Indigenous Peoples from their lands, then decolonization must include “forms of education that reconnect Indigenous peoples to land and the social relations, knowledges and languages that arise from the land” (Wildcat et al., 2014, p. 1). Aligned with the values of land education and Indigenous land-based education, Indigenous place-based education emphasizes the responsibility of humanity in living harmoniously with the natural world (Cajete, 1994; Kawagley and Barnhardt, 1999; Seawright, 2014). Discussions around the questions of who we are, where we are, how we fit in, what the place means to us, and what we mean to the place comprise Indigenous approaches to place-based education (Penetito, 2009). The characteristics of these models possess the potential to “offer epistemic resistance to domination” (p. 554) and push “settler society away from ecological damage and racial and gender supremacy and toward the cultivation of a healthy reciprocal relationship with the natural world” (Seawright, 2014, p. 571).

Bowers (2013) advocates for an earth democracy, “the right of other species to play their role in the world’s diverse ecosystems without being reduced to having only economic value” (p. 228). This concept is fundamental in Kanaka ‘Ōiwi and Indigenous worldviews—all life is sacred and all natural creation has a function (Kanahele, 2005). Eco-justice requires a paradigm shift from the dominant anthropocentric worldview (Hamilton et al., 2015) to an ecocentric worldview, which places value on all animate and inanimate entities regardless of their practicality to human beings (Kortenkamp and Moore, 2001; Leopold, 1986). In this way, ‘āina-based efforts can evolve beyond cultivating relationships to ‘āina toward challenging humanity to shape consumption patterns relative to the limitations and prospects of the local environment (Bowers, 2001; Morishige et al., 2018) and directly challenging settler power structures (Calderón, 2014; Goodyear-Ka‘ōpua, 2013). Along these lines, ‘āina-based education and other land-centered pedagogies work to reclaim and advance the languages and cultures of Indigenous learners while at the same time pursuing Indigenous educational sovereignty (McCarty and Lee, 2014).

The focus on transformation

For this study, I applied the lens of transformative praxis (Smith, 2004) that aligns with Kanaka ‘Ōiwi movements to “rebuild the structures and regenerate the systems that sustain us as ‘Ōiwi” (Peralto, 2018, p. 361). In Graham Smith’s critical analysis of a common linear representation of transformative action, based predominantly on a Western type of thinking, Smith (2004) presents a cyclical model of transformation including the components of conscientization, resistance, and transformative action to illustrate how each element may happen in any order and simultaneously at one time. The use of this transformative praxis model moves beyond identifying and critically analyzing the problems Indigenous Peoples face toward focusing on the process of transformation. Smith articulates that Indigenous educators must understand more accurately, “(a) how and why communities buy in to a transformative process, (b) what counts as transformation, (c) how we know that transformation has actually taken place, and (d) whether or not the transformation is truly beneficial” he continues to explain that the significant need is “to move beyond conscientization to change through transformative praxis” (p. 46). When transformative praxis is applied as a lens for this research, transformative action may occur as a result of approaches that center land-based literacies. The collective action people take to resist further societal and ecological damage may also actualize transformation. Driven by the research and theory around ‘āina-based pedagogies and transformative praxis, with the intent of centering Kanaka ‘Ōiwi epistemologies, this research asks the following questions: *How do we offer education to people on the ‘āina in ways that are grounded in the Indigenous knowledge systems of Hawai‘i?* And, *why implement ‘āina-based education? To what end?* While the use of ‘āina-based approaches to learning and teaching needs no justification, asking the question *to what end* envisions Kanaka ‘Ōiwi futures while explicitly identifying what constitutes transformation.

Mo'olelo as methodology

The design of this study focuses on knowledge sharing (Smith, 2021)—guided by Indigenous research methods that emphasize relationality, agency, and healing (Maunakea, 2016; Smith, 2021; Wilson, 2008). I utilize mo'olelo (Oliveira and Wright, 2016) and collaborative storytelling (Bishop, 1999, 2020) as research methods to build a collective framework for 'āina-based education. Lipe and Lipe (2017) describe mo'olelo as a methodology in this way, “Mo'olelo aku refers to the sharing of mo'olelo with another. Mo'olelo mai refers to receiving a story. Hence, the methodology of mo'olelo aku mo'olelo mai is the sharing—giving and receiving—of stories” (p. 35). Additionally, collaborative storytelling requires the researcher to engage in the research process as a participant—to bring the experiences and stories as someone positioned in the collective to weave “a mutually constructed story created out of the lived experiences of the research participants” (Bishop, 1999, p. 6). I humbly asked three Kanaka 'Ōiwi leaders if they would share their experiences in education, their approaches to 'āina-based teaching, and what they see as future implications of 'āina-based learning in Hawai'i. Rather than having a preset list of formal questions, the conversations were organic in nature, and “driven by the course of the conversation” (Oliveira, 2016, p. 79).

Each kumu has over 30 years of experience as a cultural practitioner in the Hawaiian community. They are all well known and respected as leaders in the field of education because of the educational spaces they have opened for people to learn from and through a grounded and active relationship with 'āina. All talk-story sessions occurred on the island of O'ahu and what follows are brief introductions of each kumu and a description of the setting of each conversation.

Knowledge sources

Kaleo Hanohano is a high school teacher at Kahuku High School. Kaleo has been implementing 'āina-based learning with her students since she became a teacher in the public school system in the 1990s. Kaleo is the creator of the PIKO Rubric, a guide to help teachers in Hawai'i implement place-based learning.² On May 5, 2021, Kaleo and I met online via Zoom. Our conversation lasted 1 h and 30 min.

Kamoa'e Walk is a professor at Brigham Young University where he teaches Hawaiian language and Hawaiian studies courses. Kamoa'e cares for Kahuaola, a one-acre māla'ai (garden, cultivated field) where he, his students, and the community grow a variety of native and Polynesian introduced plants like kalo, mai'a (banana), and niu (coconut). On May 12, 2021, Kamoa'e and I met at Kahuaola to share mo'olelo. Our conversation lasted 3 h.

Herb Lee is the executive director of the Pacific American Foundation of Waikalua Loko I'a, a 400-year-old fishpond in the Ko'olaupoko district. Herb has been responsible for leading the restoration of Waikalua Loko I'a since 1997. He has served as a leader in Hawaiian education, training over 3000 educators in Hawaiian culture-based, place-based, and 'āina-based teaching. On May 18, 2021, Herb and I met at Waikalua Loko I'a. Our conversation lasted 2 h.

Weaving a collaborative story

Traditionally, mo'olelo were handed down orally and the continuity of stories relied upon the listener paying keen attention, making connections, and retelling the story with accuracy (Lipe and Lipe, 2017). Oliveira (2016) explains, “Because we as researchers may learn a great deal by listening to others, especially elders and master practitioners, the sense ability of listening is commonly used in indigenous communities as a methodology” (p. 79). To honor the methodology of mo'olelo, I chose not to utilize a recorder or take notes during talk story sessions for this project. Instead, I relied on my sense ability of listening to receive the mo'olelo and my sense ability of na'au to internalize and make connections with the knowledge being shared with me (Oliveira, 2016). Ultimately, mo'olelo as a methodology in this format requires the earnest responsibility of the researcher to accurately recall the information shared. It also requires the researcher to remain accountable to the participants for how their stories will be internalized and represented.

After each talk story session, I identified and documented the lessons that I learned from each kumu and had informal discussions with each of them to share what I internalized from our conversations. The lessons learned were then woven into the form of a conceptual model. After I completed the first draft of the findings section below, I sent it to each kumu by email to read over and provide feedback. As I continued to internalize their mo'olelo and the lessons I gleaned from all three conversations, the collective story below organically emerged—meant to inform, challenge, ground, encourage, and transform all who engage in 'āina-based education.

Findings

Fig. 1 Huli Ka Lima I Lalo transformative praxis.

The naming of the framework

As a graduate student at the University of Hawai'i at Mānoa (UHM), I was committed to learning about the relationship between 'āina, education, and well-being. I also had a strong desire to continue learning 'ōlelo Hawai'i. My father insisted I learn from one of his classmates, Dr. No'eau Warner, a professor at the UHM Kawaihuelani Center for Hawaiian Language. After a few classes, Kumu No'eau asked me if I had ever listened to Kupuna Katherine Maunakea's Ka Leo Hawai'i recordings. He instructed me to make my way over to Moore Hall on the University of Hawai'i at Mānoa campus and download her interviews. He wanted me to listen to Kupuna Katherine's voice and dialect to get a sense of what a first language speaker of my 'ohana sounded like. He wanted me to pay close attention to how she spoke and the topics she brought in her interviews because there was something in her recordings I needed to hear.

Kupuna Katherine was an educator, composer, lauhala weaver, and an inspiration to the lāhui (people, nation). In the early 1970s, Kupuna Katherine taught Hawaiian language and culture out of her Nānākuli home to many of my aunts, uncles, cousins, and keiki of the community. In one of the recordings, the youths led a sharing of the songs and teachings she taught them. One of her haumāna spoke, "Nē huli ka lima i luna pōloli ka 'ōpū, nē huli ka lima i lalo piha ka 'ōpū. When your hands are turned up you have an empty stomach, when your hands are turned down you have a full stomach."³ At that moment, I knew in my na'au that the agency of turning my hands down into the soil was how I would begin to address the questions I had about my health and the well-being of my family and the disconnection I felt from the 'āina as a source of nourishment. The action of "huli ka lima i lalo" became my guide to cultivating a strong relationship and kuleana to what 'āina we did have—a few hundred square feet behind my family's home in Waipahū where my father and I, soon after hearing Kupuna Katherine's teachings, planted our first māla kalo (kalo garden).

Each of the kumu I spoke with were familiar with Kupuna Katherine and recalled dearly their time spent with Kupuna Katherine and the legacy she has left us today. Thus, I thought it was fitting to name this framework in her honor. Literally, the saying describes a state of hunger "pōloli ka 'ōpū" when hands are turned up. But if one decides to turn the hands down—to the soil, in the 'āina—fullness, "piha ka 'ōpū", is the outcome. Figuratively, this saying may guide people into the future. If Kānaka 'Ōiwi enact agency, emptiness can be transformed to abundance. Because transformative praxis was used as a lens for this research, I adapted the model to serve as a structure to explore the dynamic functions and purposes of 'āina-based education.

³"Nē huli ka lima i luna pōloli ka 'ōpū, nē huli ka lima i lalo piha ka 'ōpū" is an 'ōlelo no'eau that was taught by Kupuna Katherine Maunakea. Because this 'ōlelo no'eau was audio recorded, the word "nē" has been transcribed to match the pronunciation on the recording. However, the word "nē" is a colloquial variation of the word "ina" and although "nē" is commonly heard in spoken Hawaiian, it is uncommon in written form. This 'ōlelo no'eau can be found on the Ka Leo Hawai'i tape HV24_106A. Ka Leo Hawai'i was a Hawaiian language radio show from 1972 to 1988 with interviews and phone calls from native speakers. For more information about Ka Leo Hawai'i and to access a select number of recordings, see: <http://ulukau.org/kaniaina/>.

Four projects of 'Āina-based education

A framework of four projects that ground 'āina-based education in Hawaiian epistemology surfaced from my conversations with the kumu. I call them projects because they are meant to be meaningfully experienced and not only theorized about. At the same time, the projects are grounded in ancestral principles embedded in Kānaka 'Ōiwi epistemology. Carl Urion in [Stewart-Harawira \(2005\)](#) explains:

The traditional principles of traditional knowledge ... remain fixed and provide the framework within which new experiences and situations are understood and given meaning. As such, these principles are the means by which cultural knowledge becomes remade and given meaning in our time (p. 155).

The principles I unpack below are critical factors in 'āina-based education because they strengthen familial and reciprocal relationships between Kānaka 'Ōiwi and 'āina. By identifying these principles, Kānaka 'Ōiwi are able to frame their cultural practices and teachings within the context of ancestral values while at the same time bring the relevance of place-specific knowledge and practice to the present day.

Similar to Graham Smith's model of transformative praxis, the arrows represent how participation in each project mutually reinforces the others. Herb Lee adds that the arrows signify pilina (relationships) because relationship building is constant, iterative, and flowing. *Huli ka lima i lalo* addresses the research question of how education is offered on the 'āina. Learning from and through 'āina acts as a catalyst for the project of *kuleana* where people become conscious of and practice their responsibilities to whom they are accountable to in the context of their own positionalities. The identification and practice of *kuleana* cultivates 'āina *momona* (productive, healthy, and resilient lands, waters, and people) (Morishige et al., 2018) and the enactment of *ea* (sovereignty). Simultaneously, 'āina *momona* and the enactment of *ea* further influences the approaches used in 'āina-based learning and how people understand and carry out their *kuleana*. At the center is *ho'omana* which must occur during each project and at the same time, it is a practice that guides the learner through each project. *Ho'omana* consists of *pule* (prayer), ceremony, and opening up the mutual flow of *mana* (power) that permeates physical and metaphysical realms.

The pilina label is to recognize that transformation occurs in the context of relationships—relationships among people, within self, with natural and built environments, between Indigenous and settler traditions, etc. The pilina that connect us are innumerable whether we are conscious of them or not—as Tewa teacher and scholar Gregory Cajete puts it, “we are all related” (Cajete, 1994, p. 74). Finally, the function of decision making and policy actions is included in the framework because policies whether they are good or bad affect relationships and participation in all four projects. At the same time, engagement in the four projects transform the nature of relationships, and the way we choose to conduct our relationships may transform and inform policy actions and decision-making processes. In the following sections, the projects are described with lessons learned from each kumu I spoke with.

Huli Ka Lima I lalo

Huli ka lima i lalo is the principle and project of directly immersing oneself in the 'āina—turning one's hands down into the *lepo* (soil), *wai* (freshwater), and *kai* (ocean). The learning environments in which 'āina-based education occurs are cultural *kīpuka* where Hawaiian culture can be regenerated and revitalized in contemporary settings (McGregor, 2006). 'Āina-based education has been observed across diverse learning environments which include, but are not limited to natural ecosystems such as native forests and ocean/reef systems; restorative community food systems such as *lo'i kalo*, *loko i'a*, 'āina *malo'o*: dryland and rain-fed field systems, organic farms, *māla'ai*, community gardens, medicine gardens, food forests, and school gardens; home and community life including *wahi pana*, home gardens, public health centers, and community non-profit organizations; and academic institutions including Hawai'i's private, public, and charter schools; post-secondary institutions such as the University of Hawai'i System; and private colleges and universities (Maunakea, 2021).

Students who engage in 'āina-based learning at Waikalua Loko I'a are taught what Herb calls the 'O IA principle. It is an acronym that guides students in “O” observation of what is happening on the 'āina, “I” interpretation of what is occurring through the lenses and experiences that each learner brings with them to the 'āina, and “A” adaptation—the ability for the learner to take what is learned and adapt the teachings to solve the issues in their communities. A fundamental instructional strategy of 'āina-based education involves *kilo*, the practice of keen place-based observation. Morishige et al. (2018) explains, “Native Hawaiian knowledge systems of *kilo* support multigenerational communities to build a collective and intimate understanding of biocultural landscapes and seascapes” (p. 9). Further, they emphasize the importance of “training our memories” to be able to identify the changes in the environment; the observed changes then inform human behavior.

There are many more processes of learning and teaching from 'āina-based settings to be explored in future studies such as, *lau-lima* (many hands working together to achieve a goal), *ma ka hana ka 'ike* (learning by doing), intergenerational learning, the sharing of *mo'olelo* and *mo'okū'auhau* (genealogy), and the blending of 'Ōiwi and foreign tools to cultivate abundance (Beamer, 2014; Kealiikanakaolehaililani and Giardina, 2016; Lincoln et al., 2018). While the methods of 'āina-based education discussed above inform educators in their pedagogical practice, it is also important to bring to light the challenges faced when trying to learn from and through 'āina.

Structural issues of access

Access to ‘āina-based education is an ongoing challenge. In the Hawai‘i State Department of Education, power is concentrated in one school district that spans all islands. Bus transportation to and from schools and sites that offer ‘āina-based learning is costly and the bell schedule often prevents adequate time for students to learn at ‘āina sites. Adequate professional development opportunities for teachers on how to meaningfully incorporate ‘āina-based experiences into their classroom curriculum is also lacking (Hawai‘i Leadership Forum, 2022). The same issue resonates with Indigenous Peoples globally. In the words of Ktunaxa scholar Sam (2019), “Access to place-based language and culture, which is key to the healthy identity development of any society, is limited, and as a result, cultural continuity is at risk” (p. 10). More power and resources must be available in community settings for inter-generational transfer of knowledge systems to occur, as we see that schooling—by way of its colonial nature—often gets in the way of learning.

While Kamo‘a‘e Walk and I talked about what ‘āina-based learning looks like at Kahuaola, the story he emphasized was the barrier of Kanaka ‘Ōiwi access to ‘āina. Kamo‘a‘e challenged me to consider that while culturally sustaining and place-based approaches to education are important, if Kānaka do not have access to ‘āina to fully implement the culture-based learning they receive in educational settings, then what is the point? Hence, a framework for ‘āina-based education must include aspects of decision making and policy actions that increase Kānaka ‘Ōiwi rematriation of connection to and kuleana for ‘āina. Nevertheless, ‘āina-based learning presents a powerful tool for people to strengthen their relationships with their place and community by learning from and through ‘āina. The strengthening of relationships acts as a catalyst for the next project of kuleana.

Kuleana

What can this generation leave for the next generation? Herb Lee posed this question as a catalyst for me to think about the potential of ‘āina-based education. Herb shared a mo‘olelo specific to the restoration of Waikalua Loko I‘a. His kuleana for the past 25 years has been to restore the structure of the fishpond. The new kuleana the next generation will take up is to restore the fishpond’s ability to feed the community. Kaleo shared a story of her students almost 30 years later about the ‘āina’s ability to catalyze one’s identification and practice of kuleana. In the summer of 2019, hundreds of kia‘i (guard, protector, caretaker) stood in protection of the sacred mountain on Hawai‘i Island, Mauna Kea against proposed development of the Thirty Meter Telescope. I recount Kaleo’s story here:

Nineteen ninety-three was the year our people had our 100-year anniversary of the overthrow of Queen Lili‘uokalani. I took 100 students, we made feather leis and we marched to ‘Iolani Palace. Almost 30 years later on Mauna Kea they ran to me. “Kumu, I’m here. Do you see me? I’m staying on the mauna (mountain), kumu. We’re all here. We’re all on the mauna. Remember when you took us to Wai‘anae and you told us that we had to get into the lo‘i?” I said yes, they’re like, “Yeah, that did it for me. I was done. I was all in, that did it kumu.” You just don’t know the impact the ‘āina can make until the students have an opportunity to tell you.

At the start of her teaching career, Kaleo took her students to a lo‘i which is a traditional agricultural structure used to grow kalo. A lo‘i system utilizes gravity-fed freshwater from mountain streams or springs that flow through human made ‘auwai (ditches, canals). Freshwater flows in and out of fields feeding all the kalo before joining natural flowing streams and exiting out to the ocean. Working in a lo‘i may entail clearing debris out of the ‘auwai so freshwater can freely flow to all the kalo plants, pulling weeds so the maximum amount of nutrients is available to the kalo, and sometimes harvesting or planting.

Corntassel (2008) uses the term sustainable self-determination—a concept that advocates for the teaching of sustainable indigenous food production within educational initiatives as a foundation for self-determination and well-being. According to Goodyear-Ka‘ōpua (2013), ‘āina-based pedagogies work toward sustainable self-determination because they disrupt “the hegemonic notion that only a globalized market economy dominated by transnational corporations can provide for our needs” (p. 128). Kaleo’s students expressed how the experience in the lo‘i, with their hands turned down caring for their ancestor Hāloanakalaukapilili, was a moment of transformation for them. Not only were they cultivating kalo to feed themselves and their community, almost 30 years later, they joined hundreds of kia‘i on Mauna Kea to uphold their kuleana to protect the mountain from further development—asserting ea—their right and kuleana as sovereign Kānaka in their homeland.

‘Āina Momona and Ea

‘Āina momona refers to productive and abundant land, watersheds, and oceans. Momona means fat, fertile, or rich as in soil (Pukui and Elbert, 1986). ‘Āina momona has been articulated as the “long-term goal for biocultural restoration in Hawai‘i that speaks to the productive, healthy, and resilient lands and oceans, including the intimate reciprocal relationships our ancestors had with ‘āina ...” (Morishige et al., 2018, p. 5). Herb told a story about 3 years into the restoration of the fishpond; a teacher at a local high school called him after seeing an article in the newspaper about the restoration project. As a science teacher utilizing conventional schooling approaches, she told him that she was not connecting with her students, most of them Kanaka ‘ōpio (youth) labeled “high risk”. She wanted to bring them to learn and aid in the restoration efforts at the fishpond. The teacher, Herb, and scientists

worked together for the school year and the fishpond became an outdoor classroom. At the end of the school year, students taught community members about the restoration of the fishpond and traditional fish gathering practices. The pride they exhibited and the transformation in the students could not be denied. At the beginning of the school year, they were unsure about their purpose at the fishpond, asking the teacher, why are we here? By the end, they were proud of working together to help restore a 400-year-old fishpond and their abilities to teach others how to “throw net”. In the cyclical process of 'āina-based education, lands and oceans are restored and can continue to provide, resulting in an interdependent dynamic of 'āina momona. At the same time, 'āina-based learning presents an opportunity for Kānaka 'Ōiwi to “reconnect to 'āina in holistic ways that unify the physical, emotional, and spiritual aspects of being 'Ōiwi” (Beamer, 2013, p. 60).

Conversation with Kamo'e revealed to me that 'āina-based education can only take us so far. It is up to the individual to decide then what to do with that experience and knowledge gained. In applying 'āina-based learning in a Western system of education or trying to live as a Kanaka in the Western structure that dominates society today, we fail because of the political and structural barriers in place. In addition, the extent to which we value nohona Hawai'i—Kanaka language, culture, traditions, lifeways, determines the extent to which we choose to live as Kānaka each day. Kamo'e encouraged me to first envision in detail where we want to be as Kānaka and to let that inform what “āina-based” education entails, its processes, and what it is proposed to do.

Ho'omana

Ho'omana is the central principle and project in the framework because the mana inherent in 'āina and spiritual realms can be accessed by Kānaka 'Ōiwi through the deepening of cultural skills and knowledge, ceremony, and exercise of kuleana. Ho'omana represents power, spirituality, reverence, and the ability for Kānaka 'Ōiwi to “open the mutual flow of mana within a relationship” (Goodyear-Ka'ōpua, 2013, p. 208). This inherited and acquired mana can be drawn on to develop innovative socio-cultural structures that improve the well-being of Kānaka 'Ōiwi communities and rebuild community understandings of abundance (Enos, 2015; Maunakea-Forth and Abbott, 2015). For Herb, what started as a fishpond restoration project in 1997, guided him on a spiritual journey that has illuminated how the healing of 'āina simultaneously heals kānaka. Herb learned that 'āina-based education included four steps. First, opening oneself to akua (god, spirit, divine). Second, allowing akua to guide one's life. Third, aloha kekahi i kekahi—expressing aloha to one another and joining together to restore the 'āina. Fourth and finally, aloha 'āina—the love one cultivates for their 'āina in the continuous return, protection, and care for it. Ultimately, if we take care of the 'āina it will take care of us. Transformation occurs when one is grounded in the 'āina and open to the guidance of akua.

In our conversation, Kaleo described the kupuna teaching of ho'i i ka piko (return to the center) as having the power to connect Kānaka to the essence of Hawaiian culture and lead Kānaka into the future. Kānaka believe that people have three piko. *Piko i* at the fontanel connects them to akua and the things of the spiritual realm; *piko o* at the navel area connects them to their ancestors; and *piko a* at pelvic area connects them to the future of their people. The teaching of ho'i i ka piko taught her that her kūpuna are always with her in everything she does. Kaleo emphasized that Kānaka do not need to wait for anyone to lead them into the future, they themselves are who they have been waiting for. When Kānaka enact agency to ho'i i ka piko, they holomua—go forward with the confidence and bravery that they can capture the teachings of their ancestors, live it in the present day, and share it with future generations (Young, 1998).

Summary and discussion

Articulating what transformation looks like

I set out to address the questions of *How do we offer education to people on the 'āina in ways that are grounded in the Indigenous knowledges of Hawai'i? And, why implement 'āina-based education? To what end?* Participation in the four projects is meant to actualize transformation across diverse realms—transformation within self, community, island life, decision making, and global well-being. 'Āina-based education is a means for people to learn through and in relation with 'āina. Huli ka lima i lalo is a powerful tool, but it is only one tool that can take us only so far. Learning through and in relation with 'āina must help people identify and practice their kuleana according to their roles and responsibilities in their communities. The experiences and relationships encountered through the projects of 'āina-based education are purposed to guide decision making on personal and policy levels that ultimately enact 'āina momona and ea. Through the dynamism of the Huli Ka Lima I Lalo Transformative Praxis, settler traditions of anthropocentrism, domination, and capitalism must be identified. In the identification process, we can strategize as one community with diverse strengths potential pathways for dismantling them.

More storytelling may help share lessons learned from individuals and communities involved in 'āina-based programs on how they work toward community healing and agency, become less reliant on the global market economy, and organize to protect their places from further ecological and societal degradation. In this regard, reflecting on the following questions may help amplify Kānaka 'Ōiwi voices and beliefs pertaining to what 'āina-based education truly requires:

- What comprises the goals of Kānaka 'Ōiwi communities? What potential does 'āina-based education have in the actualization of those goals?
- What can we learn from the communities utilizing 'āina-based pedagogies to disrupt settler traditions of place and challenge dominant structures of power? Such as MA'O Organic Farms on the Wai'anāe coast of O'ahu fostering youth leadership, feeding

their community, healing the land through regenerative farming practices, and becoming stewards of more ‘āina on the Wai‘anae coast.

- Without a pedagogical focus on settler traditions of place, is ‘āina-based education at risk of being watered down or appropriated as academic institutions find extractive value in its “place-based” educational approaches?
- What work in ‘āina-based education must be done in our generation for the next generation? And by whom? Who benefits?

We have much to do for the longevity of Hawai‘i and the coming generations of ‘Ōiwi who will continue to actualize ‘āina momona, the “depth and breadth” of our ‘ōlelo makuahine, and ea in its fullness. ‘Āina-based education as a pedagogical tool can serve as a means for these actualizations; but we must be maka‘ala (vigilant, alert). Indigenous leaders remind us of the importance of *reinventing the struggle* and not to get distracting in the “sprinkling” or “cherry-picking” of Hawaiian knowledge, language, and customs which are too often appropriated by settler logic. Educators, scholars, and entities interested in ‘āina-based education must critically reflect on their instructional strategies and outcomes to gauge the appropriateness of using an ‘āina-based approach. For example, taking a college-level class outside to a māla to look at a tree is not ‘āina-based education and should not be designated as such. Reflecting on the following critical question may help avoid appropriation of ‘āina-based pedagogies:

- What does the ‘āina-based learning experience(s) entail? Why is ‘āina-based education being used in the current context?
- What outcomes do you hope to achieve? Do the outcomes advance ‘āina momona and ea? How so? Who benefits from these outcomes?
- What languages and worldviews are being advanced in your ‘āina-based learning approach? What languages and worldviews are being silenced?
- How are people being educated to sustain that which has sustained Hawai‘i prior to foreign influence?
- Are learners able to identify the settler traditions at play that perpetuate dominance and degradation in your setting?

Finally, who gets to know what? Acknowledging the extractive tendencies of settler colonial institutions, when do we engage in ‘āina-based approaches and when must we practice academic refusal? (Grande, 2015). If responses to these questions further institutional or transactional outcomes (settler power) rather than cultivate healthy relations and advance Kanaka ‘Ōiwi goals toward ‘āina momona and ea, then the use of ‘āina-based education must be reconsidered and the outcomes redefined.

He Leo Mahalo: closing with a voice of gratitude

It is people who actualize their kuleana and do the liberatory work they are doing in their communities that we join when we engage in ‘āina-based education. Kānaka who inspire me like Kaleo Hanohano, Herb Lee, and Kamoa‘e Walk. Kukui and Gary Maunakea-Forth, Kauai Sana, and Chelsie Onaga of MA‘O Organic Farms. Puni Jackson and the Ho‘oulu ‘Āina crew, the Wilhelm ‘Ohana, Dani Espiritu, and Zach Pilien of Ho‘okua‘āina. The kumu and haumāna of Hālau Kū Mana. The Kahakalau ‘ohana. Haley Kailiehu and No‘eau Peralto of HuiMAU, Maya Saffery and Kaleo Wong of Kauluakalana. Leina‘ala Bright and Keoki Baclayon of Waimānalo Health Center, Aliah Irvine, Ku‘uleilani Samson, Tiana Te Rongopatahi Mo‘iha, Uncle Eric Enos, Uncle Calvin Hoe, Ikaika Lum, Kekailoa and Makuali‘i Perry to name a few.

In closing, this story is told from a personal lens illuminated by my conversations with Kaleo Hanohano, Kamoa‘e Walk, and Herb Lee. It is specific to this time in Hawai‘i, and where I am at right now in my understanding of the purpose of ‘āina-based education—which will continue to deepen and expand as time goes on. I hope that readers are able to glean lessons from this mo‘olelo and enact their own agency to transform their current state into abundance, relation, and transformation. “Nē huli ka lima i luna, pōloli ka ‘ōpū, nē huli ka lima i lalo, piha ka ‘ōpū”.

EDITORS IN CHIEF – BIOGRAPHIES

Robert J Tierney

Rob Tierney is an international educator whose passion is for developing research partnerships to address local literacy needs with educators in different countries. Rob began his career as a classroom teacher in Australia, then proceeded to work in the United States, Canada, Australia and China. He is Dean Emeritus and Professor Emeritus of Language and Literacy Education at the University of British Columbia, the former Dean and Honorary Professor of the Faculty of Education and Social Work at University of Sydney, and a Distinguished University Professor at Beijing Normal University. In the United States, he has served on the faculties of the University of Illinois, University of Arizona, The Ohio State University, Harvard University, and the University of California. Rob has written a number of books and numerous articles on literacy especially related to global issues, diversity, and literacy development. His most recent book was entitled *A History of Literacy Education: Waves of Research and Practice* published by Teachers College Press in 2021. During his tenure as an educator, he has served as the President of the International Literacy Association, President of the Literacy Research Association, an Editor for the *Reading Research Quarterly*, the President of the Association of Canadian Deans of Education/ L'Association Canadienne des Doyens et Doyennes d'éducation, as well on a number of committees and boards for professional groups and government and nongovernment

agencies. In addition, he has been involved on a range of groups on projects globally including in Africa and Asia including for UNESCO, Children's Television Workshop, and Apple Computer.

Fazal Rizvi

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely, and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge 2010) is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge 2022) has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

**Kadriye Ercikan**

Kadriye Ercikan is Vice President of Research and Measurement Sciences at the Educational Testing Service and Professor Emerita at the University of British Columbia. She is responsible for ETS's foundational and applied research and psychometric support of ETS's major testing products and contracts, and the NAEP contract for ETS. Her research focuses on validity and fairness issues and sociocultural context of assessment. Her recent research includes validation of score meaning using response processes, use of response process data for comparing groups and examining fairness and validity of interpretation, and use of scores from artificial intelligence-based automated scoring.

Ercikan is a Fellow of the International Academy of Education. Her research has resulted in 6 books, 4 special issues of refereed journals, and over 100 publications. She was awarded the AERA Division D Significant Contributions to Educational Measurement and Research Methodology recognition for another

coedited volume, *Generalizing from Educational Research: Beyond Qualitative and Quantitative*

Polarization, and received an Early Career Award from the University of British Columbia. Ercikan has been selected to serve as the NCME Book Series Editor (2021–2026).

SECTION EDITORS

Jason Beech is Associate Professor (Global Policy) at the University of Melbourne and visiting professor at Universidad de San Andrés in Buenos Aires where he holds a UNESCO Chair in Education for Sustainability and Global Citizenship. He is senior researcher of the National Council for Scientific and Technical Research of Argentina (CONICET), and Associate Editor of *Education Policy Analysis Archives*. He has been a member of the Board of Directors of the Comparative and International Education Society (2014-2016). Jason has published extensively on the globalization of knowledge and policies related to education. He has also written and is passionate about the challenges of educating for global citizenship and a sustainable future. He has taught in several universities in the Americas, Europe and Australia.

Professor Qing Gu is Director of the UCL Centre for Educational Leadership and Professor of Leadership in Education. She is the Past Chair of the *British Association of Comparative and International Education* (BAICE), Co-Editor of *Teachers and Teaching: Theory and Practice*, Associate Editor of *International Journal of Educational Development*, a member of the Research Standing Committee of the World Council of Comparative Education Societies (WCCES), and a member of the Research Evidence and Impact Panel for the Leadership College for UK Government. Professor Gu has directed and codirected many government and research council funded projects in the areas of teacher professional development, school improvement, and systemic reform and change. She has led a £1.9 m UK Economic and Social Research Council (ESRC) funded project *Schools as Enabling Spaces to Improve Learning and Health-Related Quality of Life for Primary School Children in Rural Communities in South Africa*. Some of her books have been translated into Chinese, Japanese, and Spanish.

Professor Smith is a New Zealand Maori of Te Aitanga a Hauiti, Ngati Porou, Kati Mamoe Ngati Apa, Ngati Kahungunu descent. He is a highly regarded and internationally recognized, Maori educationalist and scholar. He has been at the forefront of transforming Maori and Indigenous social, economic and cultural conditions through re-developing education and schooling outcomes. His work links theoretical thinking and practical applications within an ongoing cycle of transforming praxis.

Professor Smith trained as a teacher at Auckland Teachers College and taught in Auckland schools. He also lectured in Education at the Auckland College of Education. He was one of the first teachers and developers of a Kura Kaupapa Maori, an alternative, Maori philosophy and principles-based School. These Maori immersion schools have grown from a single entity in 1988 to over seventy-five publicly funded schools in 2015. His theoretical leadership in the Education Department at the University of Auckland helped inform the emergence of Maori Education as a distinct field of study across the New Zealand Tertiary Sector. This work has encouraged a wide range of academic studies focused on overthrowing persisting inequities within and as a result of education and schooling in New Zealand. His significant contribution to New Zealand education is to be seen in his work related to Kaupapa Maori as a theory of Transformative Praxis. All of these elements derive from his PhD research entitled, "The Development of Kaupapa Maori: Theory and Praxis (1997)".

Professor Smith's later academic work centered on developing theoretically informed strategies related to transforming high and disproportionate levels of Maori cultural, political, social, educational, and economic marginalization. He has been a significant scholar involved in the emergence of Tribal "universities" institutions (Wananga) and is the former foundation Chair of the Council for Te Whare Wananga O Awanuiarangi. He led the successful Treaty of Waitangi Claim and settlement for Awanuiarangi. In his former position as Pro Vice Chancellor (Maori) at the University of Auckland, he was responsible for developing significant structural change within the institution while working within the Office of the then Vice Chancellor, Dr. John Hood. Notable achievements included implementing a Maori development strategy within the University which required all Deans to be responsive in their performance results for Maori and Pacific advancement; the oversight of the Proposal and winning of a National Centre of Research Excellence (Nga Pae o te Maramatanga); the initiation of the Maori and Indigenous doctoral program aimed at creating 500 Maori PhD graduates across the country in five years; the recruitment of top Maori academic scholars into the University of Auckland; the development of Kaupapa Maori as a theory of transformative praxis and which has had national and international influence. Professor Smith also served on the University of Auckland Council for three years as the Professorial representative for Academic staff.

In 2007 Professor Smith accepted a role as the Universitas 21 Distinguished Visiting Professor in Indigenous Education hosted by the University of British Columbia (within the Faculty of Education). Although the position was initially intended for two years, the role was extended for a further three years. While situated at the University of British Columbia, Professor Smith also chaired the Educational Policy Studies Department for three years. These positions allowed engagement with many Canadian universities as well as other universities across the world.

Professor Smith has made significant contributions to the political, social, economic, and cultural advancement of Maori and indigenous communities in New Zealand and around the Pacific Rim. He has worked extensively with other Native/Indigenous/First Nation's peoples across the world, including in Canada, India, US mainland (including extensive work in Hawaii and Alaska), Norway, Taiwan, Chile, Australia, as well as with selected Micronesian and Pacific nations. He is a regular contributor to national and international forums and conferences. Professor Smith has been an authoritative voice within the critical debates on *social, cultural and economic inequality* both in New Zealand and abroad, and he maintains a strong influence in the Maori/Indigenous languages revitalization movements.

Professor Smith stepped down from the administrative position of CEO/Vice Chancellor at Te Whare Wananga o Awanuiarangi in 2015 after eight years in the role. He resumed his academic research and writing career. In 2019 he was invited to take up a special Chair – Te Toi Ihorei ki Purehuroa – A "distinguished Professorial position at large" established for him at Massey University.

Professor Smith has been recognized and honored for his international contributions, receiving an Honorary doctorate (D.Litt.) from the Okanagan University College in 2005, and an Honorary doctorate (LLD) from the University of Northern British Columbia in 2013; he was elected as a Fellow of the American Education Research Association in 2014, and was awarded a Queens Honour – a CNZM in 2014. He was given the Prime Minister's Life-time Achievement Award (2017); and received the Te Ururangi National Award for Education (Matariki Awards, 2019).

Professor Smith is married to Professor Linda Tuhiwai Smith and they have one daughter and two mokopuna (grandchildren).

Therese N. Hopfenbeck is Professor of Measurement Analytics in the Melbourne Graduate School of Education, The University of Melbourne. Before starting her position in Melbourne, she was Professor in Educational Assessment and Director of the Oxford University Centre for Educational Assessment. She is a Visiting Fellow at Kellogg College, University of Oxford, elected Vice-President of *The Association for Educational Assessment-Europe* and Lead Editor of the journal *Assessment in Education, Principle, Policy and Practice*. Dr. Hopfenbeck's research agenda focuses upon bridging research on self-regulation and classroom-based assessment and making sense of international large-scale studies in education. In collaboration with Professor Nancy Perry, University of British Columbia, she is currently leading an international network of researchers disseminating classroom-based research, funded by Social Sciences and Humanities Research Council of Canada (2020–2022). She is also currently Principal Investigator for two research projects funded by IB, on critical thinking in PYP schools internationally and evaluation of education reforms in Kent, UK (2020–2022). In 2020, she led the research on Critical Thinking in the Diploma Program in Australia, England, and Norway (<https://ibo.org/research/outcomes-research/diploma-studies/critical-thinking-skills-of-dp-students/>). Dr. Hopfenbeck was Principal Investigator for the PISA (2022) study in England, Northern Ireland, and Wales, in collaboration with Pearson UK (2018–2023). She was the Research Manager of PIRLS (2016), funded by The Department of Education, UK.gov, and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019).

Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). She has advised on the implementation of formative assessment programs in India, South Africa, Norway, and the Emirates and carried out policy work for UNESCO/OECD and the Norwegian Ministry of Education Norway. Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

Nataliya Ivankova, PhD, MPH, is Professor in the School of Health Professions at the University of Alabama at Birmingham (UAB). As an applied research methodologist working at the intersection of mixed methods, qualitative, community-based, action, and translational research, she is internationally recognized for her empirical and methodological publications. She shares her research expertise through teaching mixed methods and qualitative research courses, conducting workshops and guest lectures, mentoring doctoral students and junior faculty, and serving as key personnel on funded research projects. At UAB, she directs an online graduate certificate program in *Applications of Mixed Methods Research* and oversees the design and analytical aspects of qualitative and mixed methods studies through the Center for Health Informatics for Patient Safety and Quality. She is a founding Coeditor of the *Mixed Methods Research Series* (Sage) and serves as an Associate Editor for the *Journal of Mixed Methods Research*.

Professor Jahnke is Director of Toi Kura Centre for Maori & Indigenous Education. She was the 2019 inaugural Toi o Te Wananga Fellow. Professor Jahnke holds professional qualifications in education and is cofounder and immediate past Chair of the Indigenous Peoples of the Pacific Special Interest Group of the American Education Research Association (AERA). She currently serves on the AERA Executive Committee. She was a member of the Social & Human Sciences Sub Commission of the NZ National Commission for UNESCO, the NZ Bioethics Council, the NZ Ethics Committee on Assisted Reproduction Technology, and Chair of NZ Health Research Council Ethics Committee. She is currently Cochair of the Aotearoa Research Ethics Board and a Fulbright Scholar.

Berit Karseth, PhD, is Professor at the University of Oslo, Department of Education. Karseth's main research and publications lie in the field of education policy, reforms, and curriculum studies. She has edited four books and written several journal articles and book chapters in both Norwegian and English. Her most recent publications in English include articles published in the *Journal of Education Policy*, *Scandinavian Journal of Educational Research*, *Journal of Curriculum Studies*, and *European Educational Research Journal*. Karseth was the elected dean of the Faculty of Educational Sciences at the University of Oslo 2013–2016 and is currently in the leadership team of the research group Curriculum studies, educational leadership, and governance (CLEG) at the same institution.

Dr. Kenneth Leithwood is Emeritus Professor at OISE/University of Toronto and an honorary professor at the University College London and the University of Nottingham. His research and writing is about school leadership, educational policy, and organizational change. He has published extensively on these topics. For example, his most recent books include *Leadership Development on a Large Scale: Lessons for Long-term Success* (2018, Corwin), *How School Leaders Contribute to Student Success* (2017, Springer), and *Linking Leadership to Student Learning* (2012, Jossey Bass). Professor Leithwood is the inaugural recipient of the University of Toronto's *Impact on Public Policy* award, AERA (2011) *Outstanding Leadership Researcher Award*, the 2012 *Roald F. Campbell Lifetime Achievement Award* from the University Council for Educational Administration, and the Ontario Principals' Council *Outstanding Educator of the Year* award for 2017. He is a *Fellow of the Royal Society of Canada*. A recently published bibliometric analysis found that Dr. Leithwood was the most frequently cited, highest impact educational leadership researcher in the world.¹ Research.com's 2022 Ranking of the Top 1000 Scientists in the area of Social Sciences and Humanities ranked Dr. Leithwood 70th in the world and 7th in Canada.

Xiufeng Liu is a Professor of Science Education at State University of New York, Buffalo, and a Fellow of the American Association for the Advancement of Science (AAAS). He obtained his PhD from the University of British Columbia in 1993. Before his current position, he taught high school chemistry in China, and was a tenured faculty member at St. Francis Xavier University and University of Prince Edward Island, both in Canada. From September 2020 to August 2022, he served as a program director in the Division of Research on Learning of the National Science Foundation. Dr. Liu conducts research on measurement and evaluation of STEM education and student learning of cross-cutting concepts of matter and energy. Dr. Liu is currently a Coeditor-in-chief for the journal *Disciplinary and International Science Education Research* (Springer) and an Associate Editor for the *Journal of Research in Science Teaching*, a premier journal in science education.

Margie Maaka is a Professor of Education at the University of Hawai'i at Mānoa. Her PhD is in educational psychology. She also holds professional qualifications in education from the University of Waikato and Hamilton Teachers College. She is cofounder and current Program Chair of the Indigenous Peoples of the Pacific Special Interest Group (SIG) of the American Educational Research Association (AERA). From 2017 to 2020, she served as a member of the AERA Executive Council and Chair of the SIG Executive Committee. Before that (2014–2017), Professor Maaka served as a member of the SIG Executive Committee. She has also served as a member of the Ngā Pae o te Māramatanga Center of Research Excellence International Research Advisory Panel. Her research on community-based educational renewal saw her recognized as a national scholar with the Goodlad Institute for Educational Renewal. As Cochair of the Sovereign Councils of the Hawaiian Homelands Assembly's Committee on Education, she prepared educators and educational leaders for public schools in the Hawaiian Home Lands Trust communities. Currently, Professor Maaka is committed to the preparation of indigenous educational leaders in higher education. Her research interests include community partnerships, educational psychology/indigenous educational psychology, indigenous development and advancement, educational policy, multiliteracies, and language and cognitive development.

Diane Mayer is Professor Emerita at the University of Oxford. Her research and scholarship focus on teacher education and early career teaching, examining issues associated with the policy and practice of teachers' work and teacher education.

Daniel McCaffrey is the Associate Vice President of Psychometric Analysis and Research in the Research and Measurement Science unit of the Research and Development division at ETS. Dan's research interests include the evaluation of artificial intelligence scoring of constructed responses, developing tools and methods for causal modeling, evaluating the psychometric properties of student achievement growth measures derived from annual test scores, and methods to account for measurement error in secondary data analysis. Dan received his PhD in Statistics from North Carolina State University in 1991.

Judy Parr is Professor Emerita at the University of Auckland, Faculty of Education, where she was the founding Head of the School of Curriculum and Pedagogy. A psychologist, Dr. Parr's research program is located broadly within improvement science. Her expertise is in literacy, specifically writing and its development, encompassing instructional issues like teacher knowledge and practice and the assessment of writing. Much research has been collaborative, with colleagues and practitioners within major national projects for school improvement aimed at raising achievement in literacy and, internationally, as part of funded large-scale research projects, for example in Canada and Norway. Dr. Parr has published widely in the areas of literacy, assessment, and professional learning.

Jeong-eun Rhee is a Professor of Education, Long Island University, Post, New York. Born and raised in Seoul, Korea, she earned her bachelor's degree in Educational Psychology from Ewha Women's University. In 1992, she came to the US as an international student and received an MA in Educational Psychology from West Virginia University and a PhD in Educational Policy and Leadership from the Ohio State University. As an interdisciplinary cultural researcher and educator, her recent work focuses on developing and supporting transnational, intergenerational, and decolonial feminist knowledge projects in/through antioppressive education. She recently published *Decolonial Feminist Research: Haunting, Rememory, and Mothers*, which received an honorable mention for the 2022 Qualitative Book Award of International Congress of Qualitative Inquiry.

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge, 2010), is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge, 2022), has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

Theresa Rogers is Professor of Language and Literacy Education at the University of British Columbia. Her research interests include youth arts, media and critical literacies, adolescent literature, and teacher education in literacy. Most recently she published "Youth Activism through Critical Arts, Transmedia, and Multiliteracies" in the *Oxford Research Encyclopedia*. She is author of the book, *Youth, Critical Literacies and Civic Engagement: Arts, Media and Literacy in the lives of adolescents* (Routledge) and numerous articles in scholarly journals such as *Literacy Research: Theory, Method and Practice*, *Reading Research Quarterly*, *Pedagogies*, *Language Arts*, *Children's Literature in Education* and *Journal of Literacy Research*. See: <https://ubc.academia.edu/TheresaRogers>.

Professor Chika Sehoole is a Professor of Higher Education and the Dean of the Faculty of Education at the University of Pretoria. He obtained his PhD at the University of the Witwatersrand, Johannesburg, in December 2002. In 2003/4 he was a visiting Rockefeller postdoctoral fellow at the Centre for African Studies at the University of Illinois in Urbana Champaign. In 2005/06 he was a New Century Fulbright Fellow, again, at the same university. His research interests are in the areas of higher education policy, internationalization of higher education, higher education in Africa, and teacher education. He has served in several international research projects focusing on higher education and providing expertise from the South African and African perspectives. In 2013–2017 he served as the Chairperson of the Board of the African Network for Internationalisation of Education (ANIE). He currently serves as the chairperson of the Education Deans' Forum of South Africa. He has published a singled authored book titled "Democratising higher education policy, constraints of reform in post-apartheid South Africa" by (Routledge); three edited scholarly books on higher education and more than 40 articles in journal articles, book chapters, and popular media.

Roland Sintos Coloma is a tenured Full Professor of Teacher Education at Wayne State University in Detroit, Michigan. A scholar of history, cultural studies, and education, his research addresses critical questions of race, gender, and sexuality from transnational and intersectional perspectives. His publications include *Asian Canadian Studies Reader* (2017), *Filipinos in Canada: Disturbing Invisibility* (2012), and *Postcolonial Challenges in Education* (2009). His articles have been published in top-ranked peer-reviewed journals, including *Curriculum Inquiry*, *Discourse: Studies in the Cultural Politics of Education*, *Educational Studies*, *Educational Theory*, *History of Education Quarterly*, *International Journal of Qualitative Studies in Education*, *Paedagogica Historica*, and *Race Ethnicity and Education*. He has successfully garnered over \$2 million of external funding from federal, education, and nonprofit agencies, including the US Department of Education, National Education Association, Spencer Foundation, and Schultz Family Foundation as part of the Bill & Melinda Gates Foundation's Grand Economic Challenges. Roland has served in various university leadership roles as an assistant dean, department chair, graduate coordinator, and center codirector. He was president of the American Educational Studies Association (2018–19), editor of the *Educational Studies* journal (2014–17), and program cochair of Division G (Social Context of Education) in the American Educational Research Association (AERA). He received the 2017 Distinguished Scholar Award from the AERA Research on the Education of Asian Pacific Americans SIG and the 2015 Article of the Year Award from the AERA Queer Studies and Education SIG. In 2020, he was appointed to the Governor of Michigan's statewide Asian Pacific American Affairs Commission. Born in the Philippines and raised in California, he completed his PhD in Cultural Studies in Education and Minor in African American and African Studies from The Ohio State University in 2004.

Roger Slee is the Founding Editor of *The International Journal of Inclusive Education* and *The Journal of Disability Studies in Education*. A former Deputy Director-General of Education in Queensland, Australia, he has advised governments on inclusive education policy and practice. His published books include: *The Irregular School*; *Inclusive Education Isn't Dead, It Just Smells Funny*; and *Ethics and Inclusive Education: Disability, Schooling & Justice* (with Gordon Tait). Roger was commissioned by the UNESCO to write the scoping paper for the 2020 Global Education Monitoring Report, *Inclusion and Education*. Roger also held the Chair of Inclusive Education at the Institute of Education, London, and is now the Diamond Jubilee Professor of Disability & Inclusion in the School of Sociology & Social Policy at the University of Leeds.

Ninni Wahlström is a Professor of Education at Linnæus University, Sweden. Her current research focuses on transnational and national policy discourses and their implications for national curriculum and classroom teaching from a perspective of curriculum theory and educational philosophy. Most recent publications are "School and democratic hope: the school as a space for civic literacy" in *European Educational Research Journal* (2022) and Wahlström (Ed.) *Equity, Teaching Practice and the Curriculum*, Routledge (2022).

Lei Wang is Professor and PHD advisor of the Institute of Chemical Education, the College of Chemistry in Beijing Normal University (BNU). She is also the member of Teaching Steering Committee on Basic Education of Ministry of Education of China and the director of its branch Committee on Secondary Chemistry Education, the director assistant of Faculty of Education of BNU, vice director of the Institute of Science Education of BNU, and Chairman of the Chemistry Education Committee of the Chinese Chemical Society. She is one of the chief experts in developing the *Secondary School Chemistry Curriculum Standards* of MOE. She works as the chief editor of high school chemistry textbooks (Shandong Science and Technology Press, 2004 and 2019 editions) and junior high school chemistry project-based learning textbooks (Shanxi Education Press, 2018 edition). She achieved the first prize of the National Basic Education Teaching Achievement Award, the second prize of the National Higher Education Teaching Achievement Award, and the BAOGANG Education Outstanding Teacher Award.

Everard Weber is a retired professor. He has worked in the field of education for more than 40 years. Currently he is a research associate at the University of Johannesburg (UJ) and an academic advisor in the Future Professors Programme (FPP) at UJ. He studied African Languages and History at the University of Cape Town and Comparative and International Education at Harvard University. In South Africa he has worked at Crestway High School in Cape Town, the University of the Witwatersrand, and the University of Pretoria. A recent book is *A home away from home: a community of international and South African university students*. The FPP is a government-sponsored initiative that seeks to develop the next generation of professors and academic leaders in all disciplines, across all universities in South Africa. He is in addition presently conducting fieldwork on curriculum change in South African higher education with Professor Shireen Motala and Dr. Venise Joubert at UJ. This project is grounded in the history of southern Africa and hopes to contribute to the scholarship of postcolonialism.

Ian A.G. Wilkinson is Professor in the Department of Teaching and Learning at The Ohio State University and Honorary Professor in the School of Curriculum and Pedagogy at the University of Auckland, Aotearoa/New Zealand. He has a background in educational psychology with special interests in cognition, instruction, and research methodology as they relate to the study of literacy. He served as coauthor of the influential report, *Becoming a Nation of Readers* (National Academy of Education, 1985). He was Co-Editor of *Reading Research Quarterly* from 2006 to 2012 and was inducted into the Reading Hall of Fame in 2021. His research examines the impact of classroom discussion and dialogue on students' reading comprehension and argument literacy and the implications for professional development of teachers. Recently he coauthored books include *The Most Reasonable Answer: Helping Students Build Better Arguments Together* and *Quality Talk About Text: Discussion Practices for Talking and Thinking About Text*.

David B. Yaden, Jr., PhD, is the *Jewell M. Lewis Endowed Distinguished Professor of Literacy* in the Department of Teaching, Learning and Sociocultural Studies at the University of Arizona. Prior to his present position at the University of Arizona, he held appointments at Emory University, the University of Houston, and the University of Southern California. He served as Co-Editor of the *Journal of Literacy Research*, one of the premier research journals in the field of literacy studies, and was a Principal Investigator in the federally funded Center for the Improvement of Early Reading Achievement (CIERA) where he implemented an early literacy curriculum for linguistically diverse preschoolers in inner-city Los Angeles. He also directed a statewide consortium of researchers from Arizona's major universities in the evaluation of the state's early childhood initiative to evaluate health, developmental, and educational factors contributing to school readiness. His research interests and specializations include developmental issues in early childhood education, the acquisition of literacy and biliteracy in young emergent bilingual children, family literacy, theories of reading disability, microgenetic research design, and the application of complex adaptive systems theory to growth in reading and writing.

Volume 4: Administration, Governance, and Leadership

Kenneth Leithwood and Qing Gu

© 2023 Elsevier Ltd. All rights reserved.

Introduction

While the title of this section of the Encyclopedia suggests a balanced attention to three related concepts—administration, governance, and leadership—most chapters in the section are primarily focused on some aspect of leadership. This emphasis reflects a significant trend in the field over the past several decades. It is based on a growing body of evidence indicating that the practices, values, and dispositions of those exercising a positive influence on the work of their colleagues matter more to the success of the students they serve than the structures, policies, and regulations constituting the administrative and governance systems of educational organizations. This is not to say that these systems are unimportant, just that they should aid, rather than restrain or inhibit, leaders' efforts.

This understanding, however, brings with it a substantial—some might say existential—challenge to be addressed. Administrative and governance systems are typically designed to support, to lock into place, and to reinforce widely endorsed organizational behavior; that is, organizational behavior widely endorsed perhaps today although more likely yesterday. But as preferences and expectations for what organizations should accomplish change, the value of those formerly endorsed organizational behaviors diminishes creating the need to redesign existing administrative and governance systems. Such redesign work is a big part of leadership as well, of course, as helping to determine the new preferences and expectations for the organization; these are among the most fundamental responsibilities of leadership. All chapters in this volume of the Encyclopedia have something important to say about one or both of these leadership responsibilities. These chapters also reflect prominent themes in the field's most influential scholarly journals, themes that have been widely studied over some time, but still the focus of considerable ongoing research, as well as themes that have emerged more recently but considered to be quite promising.

As a whole, chapters in this volume reflect significant, closely related changes over about four decades¹ in our understandings about how leaders successfully address the two leadership responsibilities. To illustrate, one such change concerns overall approaches to leadership—from “great man,” “heroic” leadership exercised by individuals to leadership distributed across many members of the organization, as well as other stakeholders. Another closely related change over this period is the erosion of support for “charismatic” approaches to how leaders identify and build commitment to future directions and much greater support for more inclusive, member-engaged direction-setting processes.

This decades-long period also witnessed a shift in our understandings about the nature of “instructional” leadership: from a set of practices aimed at exercising direct influence on teaching and learning, to more indirect conceptions of instructional leadership that take account of the many mediators through which the influence of leadership flows to students. This period has also witnessed a change from understanding “transformational” approaches to “leadership” as an alternative to instructional leadership to transformational leadership as a mediator of effective instructional leadership.

Some of the trends in our understandings about leadership over the past four decades have been driven by changes in our understandings about the nature of learning. Cognitive science has shifted such understandings away from relatively behavioristic conceptions toward more constructivist orientations and an emphasis on learning as a social process. This emphasis on learning as a social process has encouraged leaders' attention to the development of learning cultures, collaborative forms of work (including the formation of professional learning communities, for example), and building into the design of schools' central features of learning organizations. One key intention of such organizational redesign more recently has been to support the evolution of schools' efforts from meeting the needs of “all students” to a more intentional, targeted focus on meeting the needs of historically underserved and diverse students.

Since at least the late 1990s, educational researchers have increased their attention to better understanding how leaders' contexts influence their practices. This attention has included, among others, contexts not well reflected in the mainstream literature on leadership and administration largely dominated by research conducted in Western contexts. This attention has also included how school leaders respond to the political, professional, and accountability challenges created by incoherent, disjointed, and at times contradictory external policy reforms. The political and sociological concerns about the pedagogical challenges, professional tensions, and ethical dilemmas that education reforms have produced for school leaders and teachers are well-documented. However, an increasing body of research knowledge on successful school leadership, policy enactment, and policy coherence offers more promising, more productive and in some ways, more hopeful evidence illustrating how and why some schools have the capacity not only to survive, but also to thrive in the same context of considerable and continuing external policy demands, whilst others do not.

Chapters in this volume of the Encyclopedia are organized around seven themes. The remainder of this introduction briefly summarizes chapters within each theme.

¹The beginning of this period coincides with the “effective schools movement” which significantly increased attention to, and empirical evidence about, school leadership.

Understanding Educational Leadership

There are four chapters in this section. In the first of these chapters, Robinson argues for the distinctiveness of leadership in education as compared with leadership in other organizational sectors. This argument rests on the unique purposes of educational institutions, the consequent role-related obligations of educational leaders, and the largely unique core technologies required to achieve them. Based on a science of learning and teaching, Robinson describes some of those core technologies and the capacities needed by leader to achieve the purposes of the organizations. Myran's chapter reinforces the importance of adopting a science of learning perspective on the meaning of instructional leadership. This chapter argues that reframing instructional leadership around the science of learning is needed in response to challenges facing leaders and schools which defy simple linear, hierarchical, and cause and effect conceptualizations.

Two additional chapters explore the potential of venerable as well as more recent theories to extend or reinforce Robinson's basic argument. Ylimaki highlights tensions faced by today's schools between the culturally diverse groups of students they serve and the common standards for learning proposed for all students by the curriculum policies in many education jurisdictions.

One approach to resolving these tensions, Ylimaki believes, can be found in Dewey's long-standing philosophical approach to education which advocates for individual growth, reflection, and social development (democracy) as a way to hold the needs of individual students at tension with needs for a common societal aim toward democracy. Wang's chapter reviews four categories of theories used over the past 20 years to frame empirical studies about educational leadership recommending that such theories be both "pruned" and refined to better guide future research about educational leadership.

Leadership Practices and Effects

Chapters in this section offer a deeper analysis of the approaches to leadership—and others—briefly described in Wang's earlier chapter. Chapters by Bush, as well as by Sun, Day, and Grice, offer comprehensive accounts of those approaches and the evidence justifying their claims to be successful in furthering the interests of students in schools. Sun reviews empirical evidence about the nature and effects of transformational school leadership while Leithwood describes what is known to date about the nature and effects of "integrated leadership," an approach that combines many of the leadership practices included in both instructional and transformational leadership theories.

Chapters by Spillane and colleagues and by Harris and colleagues describe the mechanisms explaining the positive effects of distributed approaches to leadership while Lumby offers a critique of this approach to leadership and typical claims about its value. Mujis reports unclear and weak effects of both instructional and distributed approaches to leadership on international student test results.

Two chapters are centered on the position of people providing leadership. Based on the distillation of an extensive body of evidence about "middle leaders" (teachers with additional organizational responsibilities), Gurr identifies "five trustworthy statements" about the work of these leaders. Hopkins and Harris describe the position of "system leader," outline its origins, review its current status internationally, and give us a glimpse of future challenges facing those promoting this approach to leadership.

In the final contribution to this section, Branson points to the recent escalation in attention to ethical leadership practices across many organizational sectors. This chapter describes three prominent approaches to ethical educational leadership practice and identifies some of their most serious limitations and how they might be overcome.

Leadership and School Improvement

Themes explored by chapters in this section inevitably overlap themes also discussed in other sections. So, this overview is limited to identifying only those variables or strategies giving rise to school improvement found in these chapters. According to this evidence, school improvement efforts are increasingly successful when schools are encouraged to become research engaged learning organizations (Godfrey, Hubbard et al., Wong et al.) building, for example, on evidence about turnaround school processes (Liu) and making good data central to their decision-making (Datnow and Park). School leaders contribute to the school improvement process when they ensure efficient and well-targeted gathering and assimilation of information on changes occurring both within the school and in the community, complemented by effective means of the knowledge's analysis, storage, and dissemination in an effort to advance the school's interests (Qadach et al.). Decision-making should be widely distributed (Klar, Eckert, Luschei), not just with those in the school but also with the many other groups, organizations, and institutions in its surrounding environment (Hatch et al.). Improvement success is also more likely when the overall improvement process is viewed from a system-wide perspective one which surfaces the structural, cultural, and other dimensions accounting for the complexities of continuous improvement (Slegers, Godfrey, Wong).

School Leadership and Organizational Factors: Pathways to Student Learning

Most chapters in this section acknowledge the indirect nature of leaders' influence on student learning, provide evidence about possible mediating variables, and propose how leaders might influence those mediating variables. These chapters explore evidence

about five such mediating variables—learning climate, trust, alterable family characteristics, collaborative decision-making, and teachers’ sense of internal accountability.

Sebastian and Park’s chapter uses survey and administrative data to compare the effects of a handful of theoretically promising mediators on student learning. Results indicate that, among such mediators, only a school’s learning climate has statistically significant effects on student learning. Learning climate is defined in this research as an environment fostering high academic expectations and a safe and orderly climate. Building on a considerable body of research in many contexts, reported over many years, Tschannen-Moran claims that leader/teacher trust is also strongly associated with student learning. Trusting relationships between and among leaders and their colleagues helps foster commitment to a shared mission and goals. Leaders earn the trust of their colleagues when they are perceived to be benevolent, honest, competent, reliable, and open. This chapter provides guidance to school leaders about how to build trusting relations with their staffs.

Two chapters in this section explore evidence about family characteristics as important mediators of leaders’ influence on students. Jaynes’s chapter, distinguishing between alterable and unalterable family variables, asserts that educational leaders make significant contributions to student success when they: help parents learn how to express their involvement in their children’s school; adopt an “authoritative” (as distinct from “authoritarian”) parental style; demonstrate high but reasonable expectations to their children for their success at school; and acquire the knowledge they need about schooling in order to successfully advocate for their children at school. Also arguing for school leaders to become more engaged in helping parents support their children’s schooling, FitzGerald’s chapter delineates the evolution of parental involvement in a Western context leading to a broader discussion of the work of school leaders with families. This discussion includes an examination of how standards for school leadership both signal the importance of families and communities and are borrowed in international contexts. The “community school” model is described in this chapter as an illustration of a comprehensive place-based reform strategy which locates parental involvement and community engagement at the heart of equity-minded school leadership.

Schools, Ainscow’s chapter argues, have untapped potential to improve their capacity for improving the achievement of all students, particularly those from disadvantaged backgrounds. This chapter points to conditions likely to foster collaboration among all school stakeholders in the interests of using their collective capacities to foster more equitable conditions for these children. School leaders mobilize these collective capacities, the chapter asserts, by nurturing processes of social learning and knowledge creation in settings that stretch from classrooms to the committee structures of senior policymakers. Research suggests that engagement with evidence is an effective way of making this happen.

Finally, Gilbert’s chapter argues that when leaders build a sense of internal professional accountability on the part of staff, they provide staff with a source of professional aspiration, pride, and support for teacher development and their schools. Among other things, this chapter explains how such an internal sense of professional accountability can be built by establishing a collaborative culture, as Ainscow also suggests, by aligning individual responsibility, as well as by developing shared expectations and action. The chapter concludes that public and professional accountability systems should complement each other but that public accountability systems should be judged on how well they support and improve school systems for professional accountability.

The Contexts in Which Leadership Is Enacted

Chapters in this section acknowledge that what educational leaders do is significantly shaped by the circumstances in which they find themselves. There are many such consequential circumstances, for example, the nature of the students and families served by leaders’ schools, both national and organizational cultural norms, educational policies, as well as interpersonal relationships and leaders’ personal values, beliefs, and skills.

Two chapters in this section review evidence about the effects of recent policy initiatives and new expectations about school leaders’ responsibilities on their work intensification (Pollock). Such intensification, as Bauer’s chapter points out, impacts leaders’ job satisfaction, sense of efficacy, as well as feelings of stress and isolation along with knock-on effects related to principal recruitment and retention. Both chapters offer strategies for significantly reducing the negative effects of work intensification. A third chapter by Thessin and Reyes offers an extended account of one such strategy—an approach to school leader supervision by district leaders that build the capacities needed by school leaders to meet the expectation of their districts and address the ambitious policy goals most are accountable for achieving. By conceptualising policy enactment as a leadership and organisational behaviour, the chapter by Gu shows how successful secondary principals in their research have managed to broaden and deepen their organizational, social, and intellectual capacities for the improvement of quality and standards in teaching and learning, *despite* rather than *because of* externally generated reforms.

Finally, Johnson and colleague’s chapter reviews evidence about the contextual factors influencing student outcomes found specifically in Indigenous and other low-socioeconomic contexts. This evidence is used to develop guidelines for empowering Indigenous families and for positively reshaping children’s futures.

Leadership Learning and Development

This section includes five chapters primarily concerned with the nature of, and challenges associated with, formal programs for leadership development. Two additional chapters explore processes entailed in the development of a leader identity and a further two chapters review evidence about the causes and effects of two issues influencing the quality of system-wide leadership.

Chapters in this section are broadly concerned with individual leader development. Several of these chapters focus on formal program characteristics. Chapters by both Bryant and colleagues and Young, rooted in the US context, provide insights into the field's evolving understanding of educational leadership, provide efforts to professionalize the field through the development of a knowledge base and standards, and describe the work needed to build a research-based understanding of quality leadership development. Leithwood's chapter aims to foster improvements in such quality through an approach to pedagogical decision-making better aligned to learning theory; these theories should guide the pedagogical choices made by program developers. Leadership educators are advised to be highly intentional about the capacities to be developed when implementing most of the more than dozen strategies described in the chapter and not to rely on just one or a few of these strategies. Carrington describes a sample of programs and other interventions aimed at helping leaders to develop the capacities they need to foster greater equity in their schools.

Both Earley and Bubb and Sugrue and O'Sullivan advocate for an expansion of the content of formal leadership development opportunities. Earley and Bubb's chapter argues that such opportunities should devote greater attention to individual leaders' personal development, including their well-being, and develop the personal qualities and support required to function successfully in the demanding conditions now facing school leaders. Extending this position, Sugrue and O'Sullivan's chapter claims that most leadership programs do not pay sufficient attention to the intimate relationship between the personal and professional lives of leaders. Ameliorating this neglect would enhance leaders' capacities for pursuing their own values and beliefs "while seeking out legitimate compromises as they grapple with aspects of the policy environment" resulting in more professionally responsible leaders.

While most of these chapters are concerned with the development of school-level leaders, Dobson reports the results of an evaluation of the Lloyds Banking Groups school governance programs concluding that the business sector has a role to play in school governance and understanding professional development is key.

Chapters by Moorosi and Showunmi, as well as Oplatka, describe processes through which leaders come to identify and be identified as leaders. The Moorosi and Showunmi chapter devotes special attention to the role of gender in such leader formation and how the construction of leadership as a male arena influences women's opportunities for advancement and their development as leaders. Oplatka's chapter provides a framework for better understanding how leaders come to view themselves as leaders of social justice.

Chapters by Yan, Cortez Ochoa, and Thomas address three issues that have significant effects on the development of leadership across education systems, as distinct from the quality of individual leaders. Yan's chapter acknowledges the often-negative effects of excessive principal turnover across school systems and reviews the relative effects of three factors potentially accounting for such turnover—leader characteristics, school context (including low student socioeconomic status), and leaders' working conditions. Implications for future research, policy, and practice are derived from these reviews. The Cortez Ochoa and Thomas chapter explores the extent to which the setting of leadership standards and the evaluation of principals guided by such standards is a suitable strategy for encouraging their professional growth and the improvement of schools.

Perspective on Educational Leadership in Non-Western Countries

The five chapters in this section examine a wide range of leadership research interest within Latin America, China, Malaysia, Thailand, and Oman. Latin America is the broad region of interest in the chapter by Flessa and his colleagues. This chapter reports the results of two reviews of published research, the latest conducted between 2016 and 2021. Results of these reviews highlight two issues in leadership research in Latin America, namely that the knowledge base is thin and uneven across countries and there is growing interest in school leadership among researchers and policymakers in who leaders are, what they do and with what impact, and how systems recruit, support, and evaluate them.

Based on individual empirical studies and international comparative reports, Qian and Walker's chapter describes the complexity of educational leadership practices in China. This complexity is viewed as an explanation for some of the discrepancies reported in research between key features of educational leadership in China and Western education systems. Research carried out in Malaysia and described in the Adams and Periasamy chapter was conducted with more than a dozen primary school headmistresses. Complementing and extending prior research on women leadership, the headmistresses in this study stressed the importance of women leaders become visible and vocal in their systems. These female leaders had extensive teaching experience and greater knowledge than most men in their institutions about instructional matters thus equipping them to lead instructional and curriculum changes in their schools.

Kulophas and Hallinger's chapter is based on a state-of-the-art review of research about school leadership in Thailand. Results indicate that successful school principalship in Thailand is defined as general excellence in school management processes, professional recognition, and/or attainment of highly regarded professional rank. This contrasts with Western nations where demonstrated impact on school outcomes is typically identified as the dominant criterion for judging principal success. This difference is explained by Thai culture in which norms of collectivism and power distance give precedence to process over performance. This chapter describes how political and societal factors in the Thai context shape principals' values, practices, and decision-making processes.

Oman is the final non-Western context in this section examining school leadership practices. AL-Mahadi and Mohamed's chapter reports evidence of an emerging interest in "authentic" approaches to leadership in that country. More specifically, evidence

is reported about the relationship between this approach to leadership and teacher turnover intentions mediated by teacher engagement. The chapter offers directions for the improvement of school leadership practices.

Selected Conceptual and Methodological Directions for Future Research

Of the four chapters in this section, two offer conceptual directions and two offer methodological guidance for future research. Louis and Murphy's chapter summarizes research supporting the importance of school leadership behaviors that focus on developing positive relationships with members of the school community. Arguing that relationships are a foundation for student learning and development, the chapter frames the ways in which positive relationships influence the conditions giving rise to such learning and development. School leaders are central to the quality of such relationships and their efforts to build such relationships throughout their school communities are central to the contributions schools make to their students. Relationships are also a central theme in the chapter by Liou and Daly focused on networks. This chapter introduces social network theory and methods as a way to conceptualize educational leadership within interdependent systems and offers several promising directions for future research in educational leadership from a network perspective.

Two chapters in this section make the case for uses, in the future, of more sophisticated methods for conducting research (Heck) and for providing insight into patterns of knowledge production and accumulation. Heck notes that over the past several decades research in the field has become more theoretically informed, but the quality of its research methods provides relatively weak evidence for its knowledge claims. Heck's chapter makes a case for increased uses of longitudinal designs, data collection, and methods of analysis in school leadership and school improvement research in the coming decade. Hallinger's chapter provides an introduction to bibliometric methods for conducting reviews of research. A rationale is provided for this systematic review method, some of the most frequently used analytical techniques are described, and illustrations of results described. The chapter also highlights several criteria that should be considered when evaluating the quality of bibliometric reviews.

Introduction

The question posed by the title of this article goes to the heart of the theory and practice of educational leadership, for, before one can address the issue of distinctiveness, one must wrestle with the prior question “What is educational leadership?” How one answers that question will shape the degree to which educational leadership is seen as distinctive from leadership in other domains. If, for example, educational leadership is conceived as primarily concerned with forging productive relationships with staff, and the processes for doing so in schools and corporations are seen as very similar, then such similarity weakens the claim for distinctiveness of educational leadership. If, on the other hand, the work of educational leaders is conceptualized as primarily concerned with creating the conditions for the improvement of teaching and learning (Elmore, 2004), then the argument for distinctiveness is strengthened.

A great deal turns on the answer to the question posed in the title of this article. If leadership skills and knowledge are seen as generic, that is, as readily transferable from one type of organization to another (Shamir, 2013), then it makes sense to recruit and appoint leaders from non-educational organizations, waive requirements that leaders be registered teachers, and to include substantial business and management courses in leadership preparation and development programs. If, on the other hand, the skills and knowledge required to lead educational organizations are seen as particular to those organizations, then generic approaches will be found wanting, and more emphasis will be given to such things as how adult relationships are conditioned by the requirement to achieve excellence in learning and teaching (Robinson, 2006).

The position I take is that, although there are commonalities across educational and non-educational leadership, the unique purposes of the former, and the distinctive knowledge and skills required to pursue them, have been given too little emphasis. My argument for distinctiveness rests on the unique purposes of educational institutions, the consequent unique role-related obligations of educational leaders and the unique core technologies required to achieve them.

I begin with a brief review of philosophical writing on the proper functions, or purposes, of educational institutions. I then check the extent to which the three broad purposes derived from this analysis are reflected in the statements of purpose found in the policy and curriculum documents of seven jurisdictions. I argue that at least one of the three broad purposes are unique to educational institutions, and that, since the role obligations of educational leaders are partly derived from institutional purpose, educational leadership itself is distinctive from leadership in other domains. In the remainder of the chapter, I flesh out this somewhat abstract argument with an empirically based account of how the distinctive purposes shape aspects of the role of education leaders. In drawing out implications for the role, I show how successful pursuit of the purpose requires considerable understanding of the core technology—the science of teaching and learning in classrooms.

Throughout this article I treat educational leadership as distributed, in that it can be exercised by anyone regardless of whether or not they hold a formal leadership position (Robinson, 2008). My argument for the distinctiveness of educational leadership has implications for the roles of all educational leaders whether their responsibilities lie at the level of system, school, or team leadership, and whether or not those responsibilities are recognized in a formal leadership position.

The proper functions of educational institutions

Over many decades, philosophers of education have debated the purpose or proper function of educational institutions (Hand, 2014). Such debates, such as the relative importance of liberal and vocational purposes (Winch, 2002), are never finally resolved,

and a thorough discussion of them is beyond the scope of this article. The stance I take with respect to these debates is that educational institutions have several purposes and that a crucial role of leaders is to pursue them in ways that lead to their integration rather than polarization. Such integration requires not only the right philosophical commitments, but knowledge and skill in formulating curricula and pedagogies that enable integration of purposes that are too readily set in opposition to one another. After reviewing philosophical accounts of the purpose of educational institutions, I derived three purposes, which, in order to avoid using the taxonomy preferred by any particular writer, I call preparation, socialization and autonomy.

Purposes related to preparation are focused on the acquisition of valued knowledge and skills which enable children and young persons to lead satisfying and productive lives, including enabling them to make choices about the type of paid employment they desire (MacAllister, 2016; Winch, 2002). The valued knowledge and skills range from various forms of literacy and numeracy, to the specialist skills required for particular trades and professions. The importance of preparation is justified in terms of individual fulfillment (Winch, 2002), the relationship between a strong national economy and a skilled workforce (Biesta, 2009; Winch, 2002), and by the strong expectation of young people themselves that their schooling prepares them for the pursuit of fulfilling paid employment (Winch, 2002).

Purposes related to socialization are concerned with the initiation of students into particular cultures and communities, which may be associated with subject disciplines, professional groups, or political, social, religious, and ethnic traditions (Biesta, 2009). While the pursuit of such purposes is most obvious in, for example, religious schools, socialization is involved in the way in which any knowledge and skills are represented. In teaching math, for example, the subject can be taught in ways that, wittingly or unwittingly, communicate to students that the purpose of their activities is mathematical fluency i.e., to get the right answer as reliably and quickly as possible. Alternatively, math can be taught in ways that induct students into a mathematical community of practice through explicit teaching of mathematical ways of thinking and problem solving. In making these choices, educators are socializing students into very different ways of doing math and being a mathematician.

This second purpose needs little justification as it is an inevitable concomitant of pursuing the first “preparation” purpose. It is the worth of what students are being socialized into and the mode of that socialization that needs explicit debate. For MacIntyre and Dunne (2002), it is critical that students are exposed over extended periods of time to members of different traditions, so they are equipped to engage in the type of debate that characterizes an educated public. The choices educators make about socialization contribute to the formation of student identity and to the historical continuity and renewal of cultures and traditions.

My third set of purposes, which I call autonomy, has attracted the most debate among philosophers of education. For Biesta (2009), it is the counterpoint to socialization, for it involves the freedom to make choices about how to live in the world—choices that might question or even reject the cultures and traditions into which one has been socialized. According to Winch, the pursuit of autonomy in education involves developing three key personal attributes. First, as students grow older, they begin to get a sense of the kind of life they would like to lead, and so the development of autonomy involves exercising choice about how they can achieve the fulfillment they envisage. Second, students need sufficient knowledge, including self-knowledge, to make informed choices. Autonomy, in this educational sense, requires the development of a critical capacity to examine one’s life so that judgment is not surrendered to the will of others or to uncontrolled inner drives. Third, students “need to be equipped with the self-mastery to pursue projects to a successful conclusion in the face of doubts and difficulties” (Winch, 2002, p. 103).

To what extent are each of these three sets of purpose (preparation, socialization, and autonomy) found in the official statements of educational purpose of western democracies? Such statements are powerful because they signal what is valued by governing authorities and, in democratic societies, by those who elect them. In addition, such statements shape the frameworks against which curricula are developed, schools are evaluated, and their leaders are selected and evaluated.

References to preparation are found in the official documents of all seven jurisdictions reviewed (New Zealand, Victoria, California, Ontario, England, Scotland, Norway). While knowledge and skills are important, increasing emphasis is given to the integration of knowledge, skills, and attitudes into key competencies.

A competency is more than just knowledge and skills. It involves the ability to meet complex demands, by drawing on and mobilizing psychosocial resources (including skills and attitudes) in a particular context. For example, the ability to communicate effectively is a competency that may draw on an individual’s knowledge of language, practical IT skills and attitudes towards those with whom he or she is communicating

OECD (2005, p. 4).

The official documents reviewed refer to such competencies as collaboration, creativity, critical thinking, adaptability, taking responsibility and a strong sense of agency—competencies which are thought essential to living a fulfilling and productive life in the complex and uncertain world of the 21st century.

The more specific curriculum objectives that follow from the high level purposes describe the knowledge, skills, attitudes, and values that learners require to understand their world, analyze and solve problems in collaboration with others, transfer their learning to new contexts and manage their own learning. Doing history, for example, no longer involves learning screeds of facts, but understanding the structure of a discipline in which facts are organized into bodies of knowledge and engaging in the forms of historical inquiry that are particular to the discipline (Bransford et al., 2000; OECD, 2019a). Following the Committee on Defining Deeper Learning and 21st Century Skills, I call the learning involved in achieving these curriculum objectives deeper learning and use this term throughout this article. The committee defines deeper learning as “the process through which an individual becomes capable of taking what was learned in one situation and applying it to new situations (i.e., transfer)” (National Research Council,

2012, p. 5). The individual becomes expert in a particular knowledge or skill domain and knows when, why and how to apply that knowledge in solving newly encountered problems within that domain.

Far less emphasis is given in the reviewed documents to socialization and autonomy than to preparation. For example, California, Victoria, and Ontario all refer to acquisition of knowledge and skills needed to contribute to society and for life in the 21st century but make little reference to the role of educational institutions in socialization. In contrast, the English national curriculum document states that the English curriculum introduces students to “the best of what has been thought and said” (Department for Education, 2014, p. 6), and the New Zealand Ministry of Education makes the socialization purpose explicit in its vision that every New Zealander “is strong in their national and cultural identity” (Ministry of Education, 2018).

The Norwegian Ministry of Education and Research goes further by making explicit the values into which students shall be socialized in such statements as

Education and training shall be based on fundamental values in Christian and humanist heritage and traditions, such as respect for human dignity and nature, and on intellectual freedom, charity, forgiveness, equality and solidarity, values that also appear in different religions and beliefs and are rooted in human rights

Ministry of Education and Research (2019, p. 5).

Norway also stood out in its explicit reference to autonomy in such statements as “pupils and apprentices shall develop knowledge skills and attitudes so they can master their lives ...” (Ministry of Education and Research, 2019, p. 5), and “[educators] should stimulate pupils and apprentices/trainees to develop their own learning strategies and critical-thinking abilities” (Utdanningsdirektoratet, n.d., p. 2).

In summary, philosophical writings and official statements both suggest that educational institutions are charged with multiple complex purposes. While it is tempting to assume from these abstract formulations that there is tension between them (for example between socialization and autonomy), the actual degree of tension will depend on how more precise purposes are specified and on how they are pursued. For example, the pursuit of knowledge may be done in ways that indoctrinate, in which case there is considerable tension between preparation and the third autonomy purpose, or there may be little tension, if preparation is pursued through a pedagogy that is educational in the sense of cultivating reason and independent thought.

The distinctiveness of the proper functions

As Biesta (2020, p. 3) writes:

What is special and most likely unique about education is that it is not orientated to *one* purpose ... but actually is orientated to three purposes or, as I prefer to call it, three domains of purpose

Every decision about what is taught and how it is taught has implications for the quality of students’ preparation, socialization, and opportunity to think and act autonomously. For Biesta, the complexity and distinctiveness of education lies in the need to think in this three-dimensional way, because students not only learn from content, and how it is represented, but also from the quality of their interactions with their teachers. That is why he and other philosophers of education are calling for more attention to the values that are espoused and enacted in pursuit of each of the three purposes.

In my view, it is the substance of those purposes, rather than their number, that provides the stronger ground for claiming that the purposes of education are distinctive. While it could be argued that educational, religious, and cultural institutions all share a socialization purpose, only education has preparation as a major purpose. Preparation involves developing the distinctively human qualities and abilities, such as reasoning, wisdom, and understanding that enable people to manage their lives more intelligently and to appreciate the world in which they live (Pring, 2014). Only education is charged with developing students’ competencies by teaching the knowledge, skills and dispositions that are valued by a particular society, and which can, at least at secondary level, only be accessed at school.

Some may object that I have exaggerated the distinctiveness of educational institutions by overlooking the ways in which running a school is like running a business. That similarity is seen in the increasing intrusion of the language of business (e.g., inputs, outputs, targets, performance indicators, and chief executives) into education, and in calls for principals and other senior leaders to be trained in business management (Pring, 2014). Such intrusion is undeniable, particularly in those jurisdictions where decisions about budgets, staffing, property, and health and safety are devolved to the local or school level.

The necessity for some managerial work in any organization, including schools, does not undermine my claim about the distinctiveness of the purposes of education. The proper function of business is, subject to relevant ethical constraints, to produce “goods and services in such a way as to increase owner value ...” (Swanton, 2016, p. 689). The proper function of education is to educate students in ways that achieve the three purposes. The danger is that the management aspect of schools not only diverts leaders’

attention from pursuit of its educational purposes, but that its language and activities so infect the educational activities that they undermine or displace the pursuit of the educational purposes. Such displacement occurs, for example, when in pursuit of exam targets, teachers are pressured to concentrate on those students who are achieving just below the required standard, and to reduce their attention to those who are well below it (Pring, 2014). In such examples, the educational purpose of preparing all students in valued knowledge and skills is displaced by an improper purpose—increasing the school's ranking and reputation. One of the contributions of the philosophers of education discussed earlier, is their call for constant vigilance about the need to ensure that the necessary management aspects of schooling serve rather than displace educational purposes (Pring, 2014; MacIntyre and Dunne, 2002).

Deriving the distinctive work of educational leadership

In the remainder of this article, I discuss the leadership practices required to achieve the purposes of educational institutions and the extent to which they are distinctive. Ideally, this discussion would draw on empirical research on the links between leadership styles, practices, and valid indicators of achievement of the purposes. Unfortunately, this empirical strategy is limited by the fact that research on the impact of leadership on student outcomes has typically focused only on preparation, and the indicators of that purpose which have been employed to date, are far narrower than the key competencies that are so prominent in contemporary curriculum frameworks (Marzano et al., 2005; Robinson et al., 2008; Sun and Leithwood, 2012, 2015; Witziers et al., 2003.) While a program of research and development for the assessment of key competencies is underway (OECD, 2019b), it will be a long time before quantitative research will provide reliable evidence about the relationships between various types of leadership practice and the development of those competencies.

In the interim, I adopt an alternative backward mapping strategy, which starts from educational purpose, then asks how students learn to achieve those purposes, how teachers foster such learning, and how leaders can foster such teaching. The purpose on which I focus is preparation, understood as the acquisition of deeper learning. I use the science of how students learn to understand, problem solve and acquire adaptive expertise, to derive implications for teaching (Bransford et al., 2000). Once effective teaching for deeper learning is explained, I discuss some of its numerous implications for educational leadership and its distinctiveness.

This analytic strategy is very different from much of the discourse on educational leadership and management which takes theories of leader-follower relations as its starting point (Bush et al., 2019; Elmore, 2004). As Spillane (2013, p. 60) claims:

... with some exceptions, many analyses dwell on leading the schoolhouse rather than the core work of the schoolhouse. As a result, descriptions, and prescriptions for leading are only weakly related to the actual work of teaching and leading its improvement.

How students learn

There is now considerable consensus about how students learn (Bransford et al., 2000; Darling Hammond et al., 2019; Deans for Impact, 2015). Whether or not deeper learning occurs, depends, in part, on the type of academic task in which students are mostly engaged, because different tasks evoke and develop different cognitive operations (Doyle, 1983). My focus will be on comprehension tasks because growth in student comprehension and problem solving, is what is required to develop the deeper learning that is a necessary condition for building the competencies.

Comprehension and problem-solving tasks require students to actively construct a cognitive representation of the relevant concepts, events, or situations. As students gain experience in a subject domain, they develop more and better organized representations (schema) of task relevant material. Since schema are stored in long term memory, they free up limited short-term memory for the processing of new information. For students with little relevant prior knowledge—that is with few or no relevant schema—comprehension tasks create considerable cognitive overload as they struggle to bring meaning to apparently disconnected bits of information.

In short, competence in a domain requires a deep foundation of factual knowledge which is organized into a network of schema that aligns with the structure of the discipline or subject. There should be no opposition, therefore, between the learning of facts and deeper learning. The challenge for learners and teachers is to avoid memorizing disconnected facts and focus instead on their structure and interrelationships. This requires deepening learners' knowledge of the subject matter while developing their grasp of its conceptual structure (Bransford et al., 2000).

The development of expertise in a subject domain requires the encoding of valid information (Doyle, 1983). Students can develop schemata which encode faulty algorithms and concepts (Nuthall, 2007). When students have little relevant prior knowledge, or misunderstand what they have previously encountered, they will be unable to engage with tasks which presume accurate prior knowledge.

Deeper learning includes the development of the metacognitive skills required to regulate one's own learning. This involves setting goals, planning ahead, activating relevant prior knowledge, keeping success criteria in mind, and using them to monitor and adjust progress toward the goal (Bransford et al., 2000). Not all learners independently develop the internal talk that

self-regulation requires. Modern curricula require teachers to scaffold metacognitive strategies by explicit teaching and practice so that, over time, students will prompt themselves and monitor their own comprehension and problem solving. Research on metacognition shows that, as for critical thinking and problem solving, metacognitive strategies learned in one context do not readily transfer to other subject matter (Bransford et al., 2000). This means that attempts to teach generic problem solving or self-regulatory strategies are unlikely to be effective because such strategies need to be learned in conjunction with particular subject matter (National Research Council, 2012).

Academic work is conducted in classrooms in which teachers teach, not single students, but one or more groups of increasingly diverse students. Furthermore, students complete academic tasks in contexts where they are either recipients of, or witnesses to, the frequent evaluations of their teacher. For older students, these judgments contribute to a high stakes accountability system of credits or points, which determine report cards, academic pathways and, ultimately, their qualifications. These features of classrooms can create teacher-student interactions that profoundly alter students' opportunities to learn the cognitive processes required for deeper learning (Doyle, 1983). Low achieving students are likely to feel vulnerable in a highly evaluative climate and respond by withdrawal, so as to minimize the risk of public exposure and embarrassment (Peeters et al., 2020). Alternatively, they may attempt to increase their chances of success by using a variety of strategies, such as copying, and requesting detailed guides and model answers, that are designed to reduce the cognitive demands of the task. Teachers who give overly detailed instructions, prompts and advice, can unwittingly turn a comprehension task into a procedural one in which students happily follow their detailed guidance, without increasing their expertise in the subject domain (Doyle, 1986).

In short, academic work, particularly that required to achieve deep learning is complex. As Graesser et al. (2018, 9. 170), conclude:

Studies of the cognitive processes underlying academic work have revealed the enormously complex character of the operations and decisions that academic competence entails, a complexity that is often overlooked when the goals of schools are discussed.

Implications for classroom teaching

There are several excellent texts available which explain the implications for classroom teaching of how students learn (Bransford et al., 2000; Darling Hammond et al., 2019; Deans for Impact, 2015). Here, I concentrate on four implications that have particular relevance to teaching for deeper learning.

First, since what students learn is a function of the type of task they engage in, it is critical that teachers are skilled in the selection, design and assessment of tasks that are tightly aligned to the cognitive processes they intend students to develop (Tekkumru-Kisa et al., 2020). If the intended learning outcome is comprehension, then all task components, including explanations and assessments, should foster that outcome. For example, if a math teacher wants students to understand why an algebra formula works, then setting students 20 practice examples in which they apply the formula will foster procedural accuracy rather than comprehension. Comprehension is more likely to be fostered by assessing whether students can decompose the formula, apply its various steps to concrete materials, and provide a written or oral explanation of why it works.

Second, since deep learning requires the cumulative integration of prior knowledge with new information and concepts, effective teaching requires inquiry into students' prior knowledge. The purpose of such inquiry is not just to interest students in a topic, but to assess whether students have the prior knowledge assumed by the selected task and whether that prior knowledge includes misunderstandings that need to be challenged.

Third, teachers need well developed skills in managing groups of diverse learners while they grapple with intellectually challenging tasks. As already discussed, students attempt to shape tasks in ways that reduce cognitive load and, without high level skills in managing diverse learners, teachers may rely too much on memory and procedural tasks for which they are more likely to gain and retain students' cooperation (Doyle, 1983; Fulmer and Turner, 2014).

Fourth, teaching of the metacognitive skills that are required for the development of critical thinking, independence, adaptability, and other competencies, should be integrated into the subject matter students are learning, rather than presented as separate content-free processes (Bransford et al., 2000). The reason for this advice is that different metacognitive strategies are used in different subjects. For example, the types of question students ask about a word problem in math ("What pattern or principle might be relevant here?") are quite different from those they should ask in their analysis of a historical document ("Who was the intended audience?" "Why was this written in this way?"). Teachers should also be mindful that explicit teaching of metacognitive skills, even when embedded in content, adds cognitive load (Van Gog et al., 2011).

In summary, teaching for deep learning involves careful inquiry into students' relevant prior knowledge, and the provision of multiple opportunities for students to develop rich and well organized domain-specific knowledge. There should be an integration of, rather than opposition between, the learning of facts and higher order thinking, for the:

ability to plan a task, to notice patterns, to generate reasonable arguments and explanations, and to draw analogies to other problems are all more closely intertwined with factual knowledge than was once believed

Bransford et al. (2000, p. 16).

Implications for the leadership of learning and teaching

My discussion of the leadership implications of the science of learning and teaching for deeper learning is organized under five broad dimensions of leadership practice, (setting goals and expectations; resourcing strategically; ensuring quality teaching; leading teacher professional learning and ensuring a safe and orderly environment), which have been employed in empirical investigations of the effects of leadership on student outcomes. Since several reviews of the evidence on these effect effects are already available (Marzano et al., 2005; Robinson et al., 2008; Sun and Leithwood, 2012, 2015; Witziers et al., 2003), my focus will be on some of the leadership practices within each of these dimensions that are critical to supporting teachers in their pursuit of deeper learning, and on the distinctiveness of those practices.

Leading by setting goals and expectations for deeper learning

If the distinctive purposes of education are to be anything more than philosophical or policy abstractions, leaders will need to translate them into specific goals and expectations and incorporate them in relevant vision, mission, and goal statements. This goal setting activity requires a principled understanding of and commitment to the three purposes, and skill in engaging the relevant communities, so that officials, teachers, parents, and students are committed to the goals.

Success in this leadership work is certainly helped by an understanding of generic goal theory, which describes three conditions that need to be met if goal setting in any organization is to be effective. Goals need to be clearly specified, and those who are to achieve the goals must be committed to them, and have, or acquire, the capability needed to achieve the goals (Latham and Locke, 2006). But establishing these three conditions in any particular context requires much more than knowledge of goal theory. In achieving goal clarity, leaders need to clearly articulate and exemplify what they mean by deeper learning and how they believe teaching for deeper learning differs from current practice. They also need to be able to navigate the likely tensions between their own commitments and the goals that their superiors may require them to pursue (Louis and Robinson, 2012).

Teachers may value deeper learning in principle, but still not be committed to it, because their experience convinces them that success with their students is unlikely. It is critical that leaders recognize, that by setting ambitious goals, they are likely to create a gap between their teachers' current and required levels of capability. They should then initiate respectful and non-blaming discussion of the capability issues so that teachers trust that they will get the help they need (Robinson, 2018).

An important distinction is made in goal theory between performance goals and learning goals (Latham and Locke, 2007). When teachers' and leaders' current capability is not sufficient for achievement of a performance goal (e.g., student achievement in math problem solving will improve by 25% in a given year), leaders should set prior learning goals (e.g., all teachers at a particular grade level meet criteria for effective teaching of the vocabulary and strategies relevant to a type of math word problem). Learning goals create an expectation of, and accountability for, teacher and leader acquisition of the knowledge and skills required to achieve the performance goal. If leaders set performance goals when capability is insufficient, they are likely to create stress, lower commitment and invite goal displacement. Pressure to achieve performance goals that are beyond teachers' current capability, combined with high stakes accountability, invites gaming and other forms of unethical behavior (Welsh et al., 2019).

The three principles of goal theory are generic, in that they are applicable to the leadership of any type of organization. However, as I have illustrated, their successful application in education requires leaders who can integrate their knowledge of goal theory with distinctive educational knowledge and skills. For example, leaders need to be able to articulate and defend their choice of goal (deeper learning), evaluate the match between the required and current pedagogies, and provide a compelling account of how any capability gap will be closed. The knowledge and skills involved are distinctive to the work of educational leadership.

Leading by resourcing strategically

Enabling all students to succeed in deeper learning requires leaders to be very strategic in their management of the key resource of students' time. My focus on this resource is not intended to belittle the importance of the more typically discussed management of human, material, and financial resources (Mestry, 2019). Rather, it is to emphasize that students need multiple and varied opportunities to learn challenging material and, for those students whose homes do not provide the cultural and educational capital required to engage with such material, school provides their only opportunity to do so. Rushing through an over-crowded curriculum prevents the pedagogical approaches, such as respectful inquiry into students' emerging understandings and misunderstandings, that are essential to the goal of deeper learning.

One way to understand the use of students' time is via the construct of opportunity to learn (Berliner, 1987). Leaders can monitor students' opportunities to learn by inquiring into the quantity and quality of the opportunities that are planned and provided (Miles and Frank, 2008). Students' opportunities are eroded when time is lost through suspension of regular classes, pull-out programs, extracurricular activities conducted in class time, disciplinary removals from class and other disruptions. The quantity of opportunities is also reduced when teachers do not teach the planned curriculum because they believe that their students are not ready for such learning or because they lack confidence in teaching the scheduled lesson.

More subtle erosions of opportunities for deeper learning occur when there is misalignment between lesson activities and resources and the intended learning outcomes. Even when carefully aligned, students' opportunities are eroded if they lack the prior knowledge to engage with cognitively demanding tasks or they are bored by material they already know. Finally, opportunities to learn are eroded when, despite cognitive engagement, students experience repeated lack of success.

The management of students' time should be informed by rich feedback from students themselves about the pace and intensity of their learning. Such feedback, combined with opportunities to take control of portions of their own timetable, builds the meta-cognitive skills involved in becoming a self-regulated learner, and the autonomy that is one of the three purposes of educational institutions.

The strategic management of students' time so they have the quantity and quality of opportunities needed to succeed on complex tasks is a critical and much neglected aspect of educational leadership. The generic knowledge and skills involved in time-tabling, and the management of materials and money, need to be conditioned by distinctive educational knowledge and skills about how to allocate those resources in ways that ensure deeper learning (Miles and Frank, 2008).

Leading by ensuring quality teaching for deeper learning

Improving the overall quality of teaching for deeper learning, including reducing undesirable variability in such teaching, requires leaders at all levels in a school to be skillful, consistent, and persistent in monitoring and improving curriculum and pedagogy. Improvement should be based on a shared understanding of what teaching for understanding would look like in a given curriculum area and of how current curricula and pedagogy—as planned, delivered, and experienced by students—measure up to that standard. A key question for leaders is “Does the curriculum, as experienced by students, provide multiple opportunities for them to develop well organized bodies of knowledge, rather than discrete facts and isolated skills?”

A good starting point for addressing this question is an analysis of the types of academic task teachers are setting and assessing. The objective of such analysis is not only to assess the extent of focus on higher order skills such as comprehension, problem solving and critical thinking, but, more importantly, to understand the barriers to teachers setting, and students completing, tasks that require such skills. Since it is the assessments that students experience as the real tasks, alignment of intended and assessed learning outcomes is vital (Doyle, 1983; City et al., 2009). Light sampling of planned and completed assessment tasks provides an evidence base from which teachers and their curriculum leaders can discuss the cognitive processes being assessed, their alignment with deeper learning goals and the reasons for any misalignment.

A second focus for an evaluative review could be the depth and breadth of the current curriculum. Depth is needed because students need multiple and varied exposures to concepts, in order to develop schema that encode underlying principles and inter-relationships. Curricula that are too broad prevent learning for understanding because such learning takes more time than rote learning or the application of procedures. Leaders need to directly and collaboratively address the dilemma teachers often experience between fostering the in-depth learning that they espouse and covering the curriculum, for it is this dilemma that often stops them from narrowing and deepening their curriculum focus (OECD, 2019a).

A third focus for an evaluative review is the match between current teaching approaches (pedagogy) and those required to teach for understanding and critical thinking. It is critical that leaders have enough knowledge of and access to evaluative research on pedagogy to challenge the pedagogical fads and fashions that bedevil education and contribute to inequitable student outcomes (Bransford et al., 2000). For example, 50 years of research in cognitive and educational psychology has provided compelling evidence that novices are more likely to learn and transfer their learning if their teachers provide them with fully guided instruction rather than leave them to discover critical information for themselves, as happens in the various forms of discovery, inquiry, experiential and problem-based teaching (Clark et al., 2012). These discovery-based pedagogical strategies have minimal or detrimental effects on learning outcomes, because students lack the prior knowledge needed to make sense of the activities through which they are supposed to discover the intended understandings (Bransford et al., 2000; Van Gog et al., 2011).

A fourth focus for an evaluative review could be the instructional infrastructure that leaders employ in supporting the work of their teachers. The key question leaders should ask about the school's instructional framework, teacher induction handbook, teacher evaluation and classroom observation procedures, protocols for team meetings and sharing of teaching tips and best practice, is whether these tools and routines are fit for the purpose of improving teaching for deeper learning. For example, do classroom observation protocols require information about teacher inquiry in general, or is a distinction made in the protocol between teacher inquiry for an answer, for the right answer or for students' reasoning? It is only the latter type of inquiry that serves as an indicator of teaching for understanding and deeper learning.

The leadership knowledge and skills required to ensure teaching for deeper learning are deeply embedded in and distinctive to educational theory and practice. Because they are more extensive than can be reasonably expected of any one leader, the goal should be to enrich the knowledge and skills that are distributed across, and available to, all leaders of teaching and learning.

Leading and participating in teacher professional learning

By embracing the goal of deeper learning for all students, leaders are likely to create a considerable gap between the current and required capability of some of their teachers. Closing this gap is essential if leaders are to address inequities in students' understanding and problem solving. Doing so requires sustained, targeted, and high-quality opportunities for teacher professional learning. Such opportunities include both formally scheduled and resourced teacher professional development and the more informal on-the-job teacher discussion and feedback that is part of a learning-focused teacher culture.

A recent meta-analysis of the evidence on the effectiveness of formal teacher professional learning suggests that it brings little payoff in terms of improved outcomes for the students of the participating teachers (Filges et al., 2019). A likely explanation for these dismal results is that few professional development interventions are designed in accordance with our knowledge of how people learn. Since the science of learning is the same for students and adults, the applicable principles are those summarized in

the earlier section on student learning. Like their students, teachers need multiple opportunities to learn, transfer and apply the complex ideas and skills that are needed to teach diverse groups of students how to problem-solve in particular subject domains. This means that a formal professional learning program should be tightly focused, rather than the mile-wide and inch-deep provision that is still seen in some schools.

The teacher learning agenda should be highly responsive to the evidence about what students have yet to learn (Elmore, 2004). It should also be informed by diagnostic evidence about the links between what students learned and how they were taught (Bryk et al., 2015). Well-designed teacher professional learning includes respectful inquiry into the knowledge and beliefs that inform teachers' practice, because, just as for students, teachers' prior knowledge will interact with and profoundly affect how they understand and implement any new practices (Robinson, 2018).

Leaders need to be skilled and knowledgeable in explaining why professional learning is not voluntary, why meeting some student learning needs are given priority at this time over others, and why the leaders of each professional learning opportunity are chosen based on task-relevant expertise rather than on years of experience, nomination or formal position (Elmore, 2004). Leaders with deep educational expertise will defend such controversial decisions, by providing educational grounds for them. Leaders who lack such expertise cannot draw on this important source of leadership influence, and must rely instead, on the force of their personality and positional authority (Fay, 1987). When leaders rely on generic influence processes their leadership becomes more managerial and less educational.

Leading by ensuring a safe and orderly learning environment

Viewed from an educational rather than a narrow behavior management perspective, the work of creating a safe and orderly school is about increasing the behavioral, cognitive, and emotional engagement of students by meeting their needs for personal competence, a sense of belonging and control over and success in their learning (Wang and Holcombe, 2010). There is a considerable body of research on how school and classroom structures, routines and norms are perceived by students in ways that differentially impact their engagement. For example, if the preparation purpose of education is pursued through performance goals, the resulting high stakes competitive environment is likely to threaten students' need for personal competence and reduce their cognitive and emotional engagement with school. If, on the other hand, leaders ensure an emphasis on self-improvement through mastery or learning goals, then students are likely to make greater effort, including more use of self-regulation strategies (McInerney, 2011).

Students' need for autonomy and control over their learning is fostered by such things as student involvement in formative assessment processes, meaningful participation in school decision-making and choice about how they participate in school sports, cultural and arts activities. Their sense of belonging is fostered by confidence that their teachers understand and care about them (Bryk et al., 2010).

The academic tasks that are required for deep learning pose particular challenges to maintaining safe and orderly learning environments, because the answers to such tasks cannot be predicted and rehearsed in advance. Students may attempt to reduce their probability of failure by resisting, dissembling, or negotiating a reduction in the difficulty level of the task or its assessment. In an attempt to establish or restore order, teachers may simplify the task or select those which are more familiar and easier for students. It is important that leaders understand that their teachers cannot increase opportunities for deeper learning until they are able to integrate the provision of such opportunities with maintenance of an orderly class. As Doyle (2006, p. 111) writes:

... academic work can be swamped by the management function in teaching, and teachers can become preoccupied with getting work accomplished rather than promoting student achievement.

Since classroom order is a function of the interactions between teachers, students and academic tasks, leaders should help their teachers to diagnose the source of the difficulties before suggesting solutions. Is the cognitive load associated with the task excessive because the students lack the relevant prior knowledge (Center for Education Statistics and Evaluation, 2018)? Has there been too little explicit instruction in the relevant concepts with students expected to discover them on their own (Clark et al., 2012)? Or is the problem one of classroom management (e.g., poor classroom routines or unclear and inconsistent teacher expectations (Doyle, 2006)?

Leaders can help teachers reduce students' feelings of vulnerability and threat by showing them how to reduce cognitive load through explicit teaching of relevant prior knowledge. Similarly, they can help teachers to reduce evaluative threat through non-evaluative inquiry into several students' thinking and using the resulting information to give formative feedback to the group rather than to each individual student. They can model and develop teacher inquiry that assesses the impact of teaching rather than the correctness of the students' answers. Such strategies, if used consistently, will reduce the psychological risk students attribute to engaging with challenging academic tasks and increase their behavioral and cognitive engagement.

In pursuing a safe and orderly environment, leaders' focus should not be on classroom misbehavior per se, for such disruptions are usually symptomatic of teachers' and students' difficulties in establishing and maintaining the routines required to sustain attention on challenging academic work. The focus of leaders should be on inquiring into the source of student disengagement and assisting their teachers to create those classroom norms and routines that foster student engagement and success.

Concluding remarks

In this article I have argued that the preparation purpose of educational institutions is distinctive and that it is this purpose, expressed in contemporary policy and curricula as the promotion of deeper learning along with its associated competencies, that confers the distinctiveness of educational leadership. Given this purpose, I have argued that much of the work of educational leadership should be derived from the science of how students learn in classroom contexts, and of how teachers teach for deeper learning. That knowledge shapes the distinctive features of educational leadership and creates an extensive learning agenda for current and future educational leaders.

While the current emphasis on instructional leadership has moved the field from its reliance on more generic leadership theories, my argument suggests that more attention is needed, within the instructional leadership tradition, to the implications of pursuing ambitious deeper learning goals. Achieving those goals (e.g., high levels of understanding, complex problem-solving, metacognitive and collaborative competencies) is hugely challenging for learners and teachers, and unlikely to be achieved in settings where leaders do not have access to and utilize the science of learning and teaching for understanding.

Some might argue that, since most leaders are experienced teachers, they will have sufficient knowledge of the science of learning and teaching on appointment, and what they need is the more generic leadership skills involved in such things as setting goals, recruiting staff, and financial management. I have two responses. First, the extent to which leaders have the relevant knowledge on appointment is an important empirical question, answered by research on such things as the extent to which they can lead a discussion on the implications of cognitive load theory for pedagogical choice. Second, my argument for the distinctiveness of educational leadership does not imply that it has nothing in common with leadership in non-educational institutions. In my discussion of the five dimensions of leadership, I outlined how generic leadership skills such as goal setting, were important, but needed to be integrated with the particular educational constraints required to achieve the overarching purposes of today's educational institutions. Such integration transforms the decontextualized abstraction of generic leadership into a situated, distinctive, and content-rich process. If my account of educational leadership is accepted, then it opens up rich possibilities for research and development programmes on the knowledge, skills, attitudes and values which will enable educational leaders to succeed in the distinctive and highly challenging work that their roles entail.

Re-conceptualizing instructional leadership through a science of learning lens

Over the past 30–40 years the emphasis on the impact of instructional leadership on student learning has gained increasing attention in both the scholarly and applied literatures (e.g., [Glickman et al., 2001](#); [Hallinger et al., 2020](#); [Hornig and Loeb, 2010](#); [O'Donnell and White, 2005](#)), becoming a nearly ubiquitous component of the school leadership field ([Hallinger et al., 2020](#)). Born in part out of the theory movement ([Halpin, 1958](#)), what some called the *New Movement* ([Greenfield and Ribbins, 2005](#); [Hughes, 2004](#)) in the middle of the twentieth century, and more pointedly, the effective schools movement ([Edmonds, 1979](#)) that followed, this literature highlights that school leaders who develop strong instructional leadership skills can have a marked impact on student learning. Specifically, school leaders who develop the capabilities to observe, assess, and identify needed instructional supports for students and teachers, to give feedback that helps teachers to iteratively improve their practice, evaluate curricular materials, identify and provide needed professional development opportunities, and lead systemic change are said to positively impact student performance (e.g., [Graczewski et al., 2009](#); [Leithwood and Seashore-Louis, 2011](#); [Olsen, 2006](#); [Robinson, 2010](#); [Steele et al., 2015](#)). Instructional leadership is concerned with what happens in the classroom ([Brazier and Bauer, 2013](#)) and is focused on improving the classroom practice of teachers ([Leithwood et al., 2004](#)) and as such, is focused on the organizational conditions that support student learning.

Nonetheless, while the literature provides bold language about instructional leadership, emphasizing a robust vision of research based teaching and learning ([Brazier and Bauer, 2013](#)), and a combination of philosophy, knowledge, and action ([McGhee and Lew, 2007](#)), the literature offers limited examples of precisely what this looks like ([Brazier and Bauer, 2013](#); [Neumer-ski, 2013](#)), and has been poorly defined ([Louis et al., 2010](#)). Much of this research has focused on what effective leaders “do,” not on how they think about what they do ([Stein and Nelson, 2003](#)), and the epistemic view of the student in most instructional leadership models overlook or ignore the reciprocal role of the students themselves. While it is well excepted in the broader educational administration literature that leadership has an impact on student learning, scholars and practitioners have struggled to define instructional leadership, allowing the concept to be interpreted and used in expansive ways ([McGhee and Lew, 2007](#)). Moreover, instructional leadership has been conceptualized, in large measure, through studies of school principals' experiences and perspectives and reified through current leadership roles and practices ([English, 2012](#)). Many of the most cited works on instructional leadership are consensus building articles that review the current models to develop a unified framework of existing research ([Hitt and Tucker, 2016](#)).

Despite broad intuitive and research based connections between instructional leadership and student learning, the knowledge of how instructional leadership impacts student learning is limited (Neumerski, 2013; Shaked, 2021). Similarly, because it has been operationalized so broadly it can be ambiguous and unobtainable (Brazner and Bauer, 2013; Rigby, 2014; Salo et al., 2015). Perhaps most importantly much of this research has tended to conflate student performance outcomes with learning, which is a an overarching challenge for the broader field, with notable practical and theoretical implications (Soderstrom and Bjork, 2015). This conflation of learning for performance risks allowing “surface level compliance oriented performance on standardize test to suffice for engaged, deliberative, meaningful, enduring, and transferable learning” (Myran and Sutherland, 2019a). In addition, the conceptualizations and definitions of instructional leadership don’t address how these leadership competencies and actions impact the actual cognitive and affective behaviors of students and as such, understanding the nature and quality of the learning experience and the learning “outcomes” is difficult to ascertain.

This conflation of learning and performance reveals the incongruence between the normative views on learning found in this literature and the empirical study about learning and motivation found in the learning sciences (e.g., educational, cognitive, and developmental psychology). This lack of a clearly defined operational definition of learning and the nature of the influence that instructional leadership has on students’ cognition and learning outcomes allows these gaps in knowledge to be filled with the assumptions of the prevailing logic, folk epistemologies, and social consensus (Anderson, 2001; English, 2000; Myran and Sutherland, 2019b), reinforcing “the normatively desirable role for principals who wished to be effective” (Hallinger, 2010, p. 5).

Leadership content knowledge – bringing specificity to instructional leadership

Bringing greater context and specificity to theories of instructional leadership, Stein and Nelson (2003), pointed out that all instructional leadership skills and knowledge are situated in the subject matter being taught and therefore, the leader’s knowledge of content will sharpen the lens through which they look at, understand, and support instruction and learning. Building from the growing interest in teacher pedagogical content knowledge (Shulman, 1986, 1987), which emphasizes a confluence of strong content knowledge and appropriate pedagogical knowledge needed to teach that specific content, Stein and Nelson (2003) introduced the concept of *leadership content knowledge* (LCK). Leadership content knowledge emphasizes that principals and other school leaders not only need to be conversant in the skills and knowledge associated with instructional leadership, but to developed fluency with the content being taught (Steele et al., 2015). However, little is known about how leaders’ LCK intersects with other instructionally and learning focused efforts to support teaching and learning (Quebec Fuentes and Jimerson, 2020), and the empirical evidence of its impact on teaching and learning is limited.

Moreover, like the broader work in instructional leadership, LCK also conflates performance outcomes with learning and does not conceptualize how this construct impacts students cognitive and affective learning behaviors. In this way, the construct, while compelling on a number of levels appears to sidestep the issue of how LCK influences the actual cognitive and affective behaviors of the students themselves. The impact is indirect, leaving important nuances about learning found in educational psychology and the related learning sciences, underexplored.

The crossroad between scientific management and facilitating learning

Myran and Sutherland’s (2019b) identification of the incongruence between educational leadership’s historic grounding in scientific management and managerial principles and the robust science of learning found in educational psychology and the related science of learning, may offer a means for identifying an underexplored antecedent to these challenges.

They point out that these differing theories of action represent competing conceptualizations about the nature of learning. On the one hand, the prominent managerial paradigm tends to frame learning as a linear, one-way delivery of content to students who in turn passively receive this content. On the other hand, the science of learning has painted an increasingly clear picture of the complex, dynamic and reciprocal interaction between the learners active and deliberate agency, their introspective capabilities, and the school’s social, ecological, and epistemological conditions. The first framing students as receiving an education, and the second framing student’s agency at the center, and the school and social conditions as reciprocally and bidirectionally interacting to foster learning. This differentiates structures that *produce* learning with those that *facilitate* learning (Myran and Sutherland, 2019b).

In this way, I argue that instructional leadership sits at the crossroads between long standing scientific management influenced habituated norms and assumptions about the goals and purpose of educational leadership and the growing push for school leaders to be managers *and* instructional leaders. Salo et al. (2015), described this as being at the “center of professional crossfire, between, on one hand, management practices built on efficiency, accountability and consumer orientation and, on the other, a collegial culture of trust and professional traditions built on ideals of democratic citizenship” (p. 494), what Moos et al. (2004) refer to as the “cross pressures” that school leaders face in their daily work between management and facilitating learning.

In short, if the prominent paradigm is grounded in principles of efficiency, uniformity, and productivity, then so too are the language, theories, metaphors, and strategies used by the field. How can we define and operationalize instructional leadership and leadership content knowledge with the language, theories, metaphors, and strategies of scientific management?

Even as the field has continued to evolve the specific understandings of how school leaders may influence the instructional climate and impact student learning, beyond lists of leadership traits and general behaviors (Neumerski, 2013), largely derived from professional consensus (English, 2000), we lack understanding of the process of how school leaders impact student learning

in their daily work and how these processes scaffold students cognitive and affective behaviors. If we are to address the challenges of refining our understanding of how school leadership shapes the instructional climate in ways that promote student learning, we need to reframe the narrative, metaphors, and strategies around a more appropriate science, that is the science of learning.

Purpose statement

In this chapter I identify the incongruence between our field's grounding in scientific management and the science of learning and how these disjunctures have shaped our conceptualizations of the school leaders' role in supporting instruction and student learning. Drawing from the related traditions of problem identification, theory building and thinking with theory, I unpack the instructional leadership and leadership content knowledge literatures and examine it through [Myran and Sutherland's \(2019b\)](#) framework to reveal the potential antecedents to the cross-pressures experienced by school leadership seeking to both manage and facilitate learning. The emergent focus on learning found broadly in the educational leadership field, and more specifically in the instructional leadership and leadership content knowledge literature appears to hold great promise for not only facilitating learning in general, but as a means of further addressing long standing structural and historic learning inequities. However, I build an argument that unless we address the various incongruences identified by Myran and Sutherland, we will continue to struggle to evolve these constructs to be better aligned to our field's core purpose and fail to achieve their potential.

Reinforcing this perspective, as [Bandura \(1985\)](#) stated, "what theorists believe people to be determines which aspects of human functioning they explore most thoroughly and which they leave unexamined. Conceptions of human nature thus focus inquiry on selected processes and are in turn strengthened by findings of paradigms embodying the particular view" (p. 81). In this way the more deterministic means by which our field has framed the role of school leaders in shaping student learning reifies these instrumental and functionalist perspectives and in turn constrain the epistemological, ontological, and methodological approaches to exploring these relationships. This chapter offers a means of unpacking the conceptualizations of leadership's role in shaping student learning, identifying the constraining incongruences, and reconceptualizing it through a science of learning lens.

The missing paradigm

As [Shulman \(1986\)](#) highlighted regarding the development of teacher pedagogical content knowledge, so neglected in the scholarly and applied fields was teachers' subject matter knowledge that they called it the "missing paradigm" in research on teaching. This seems to me a sort of counter-managerial pronouncement, an assertion that teaching is more than the delivery of standardized and codified content to passive students. I build from this notion of the missing paradigm, suggesting that the science of learning is the missing paradigm in educational leadership broadly, but specifically for instructional leadership.

In previous research, my colleague and I suggested that there is a fundamental paradox between the historically and conceptually rooted managerial leadership paradigm and our growing understanding about the principles and theories of learning found in the learning and psychological sciences ([Myran and Sutherland, 2019b](#)). We argued that even with the increased interest in more student centered outlooks about leadership and schooling, there is a tendency to replicate the linear cause and effect, hierarchical, and "decidedly functionalist and positivistic", if not "exclusively functionalist and instrumental view of the principal's role" ([Hallinger and Heck, 1996](#)). Offering a gestalt synthesis of the rich research on learning and motivation, we suggested that these managerial proclivities represent substantive departures from theories of learning and without a robust understanding of the theories and science of learning, we will continue to be tethered to a frame of reference that is antithetical to the core purpose of schooling – that is learning.

Methods: problem posing, thinking with theory, and theory building

As [Sarton \(1929\)](#) emphasized, "the most difficult thing in science, as in other fields, is to shake off accepted views" (p. 88). Framed within this challenge, I draw from [Myran and Sutherland's \(2019b\)](#) call to reframe the leadership narrative around the science of learning. Using theories of learning as a counter-managerial lens for understanding the reciprocal nature of human interaction, learning and knowledge creation, I engaged in deep problem identification utilizing the concept of *thinking with theory* ([Jackson and Mazzei, 2011](#)) to explore areas where instructional leadership and leadership content knowledge might continue to advance beyond the confines of the managerial project and its functionalist and instrumental assumptions about learning.

Specifically, I draw from problem posing/identification strategies ([Brown and Walter, 2012; Freire, 2013, 2021](#)), that have a strong focus on criticism and problematizing unrecognized or under-recognized assumptions and their implications and consequences ([AERA, 2009](#)), thinking with theory ([Jackson and Mazzei, 2011](#)), as a means of offering strong theoretical basis to problematizing challenging problems of practice and theory building methods ([Lynham, 2002; Lewis and Grimes, 1999; Gioia and Pitre, 1990](#)), as a means of offering new or refined theory that is better conceptualized to address the identified theoretical problems and problems of practice. I conceptualize the use of these related constructs as reciprocal; building on each and offering iterations of improved problem identification and the development of theory that is better adapted to the primary goals of organizational improvement and student learning.

Thinking with theory: using the Myran and Sutherland's synthesis of the science of learning as an analytic lens

First, in framing my use of theory as central to my analysis, I emphasize that theory shapes how we see, experience, and think about the world, whether we are cognizant of the specific theory or theories at work or if they are implicit to the cultural or organizational norms that shape our understanding of the world. In this way, thinking with theory allows us to be explicit about the various theories that are both knowingly and unknowingly at work in shaping our understanding of a given phenomenon. Moreover, thinking with theory provides a pathway for rigorously exploring new, and potentially more adaptive ways of understanding a given phenomenon and to “shake us out of the complacency of seeing/hearing/thinking/feeling as we always have ...” (Jackson and Mazzei, 2011), to make plain the epistemological and ontological assumptions that undergird and constrain how we see and understand the world (Jackson and Mazzei, 2011), and as a form of sensemaking (Weick, 1995). Similarly, theory offers a means of scaffolding for testing, adapting and refining theories in use and theories in action (Argyris and Schon, 1974).

A gestalt synthesis of the science of learning

In short, Myran and Sutherland's gestalt synthesis of the science of learning held that since the cognitive revolution some 70 years ago, compelling counter-managerial evidence describes learning and motivation as driven by the active, deliberate, and introspective agency of the individual which is reciprocally situated within complex and dynamic social contexts that serve to mediate, shape, or constrain the construction and co-construction of knowledge (Myran and Sutherland, 2019b). In this way, the learner is not the product of what schools and educators do. Instead, “the individual's behavioral, cognitive, and introspective capabilities interact bidirectionally with the environment and function as mediating factors that shape and constrain how one interacts within social structures. In this way, “we are both products and producers of our own learning environments” (Myran and Sutherland, 2019b). As Bandura (1989) highlights, “persons are neither autonomous agents nor simply mechanical conveyers of animating environmental influences. Rather, they make causal contribution to their own motivation and action within a system of triadic reciprocal causation. In this model of reciprocal causation, action, cognitive, affective, and other personal factors, and environmental events all operate as interacting determinants. Any account of the determinants of human action must, therefore, include self-generated influences as a contributing factor” (p. 1175).

Incongruent paradigms

Similarly, Myran and Sutherland (2019b) highlighted the disjunctures between the above gestalt synthesis of learning and the prominent managerial paradigm. They emphasized that the impacts of the science of management can be seen in its primary focus on the efficient and uniform operation of schools (Tyack and Cuban, 1995; Tyack, 1974), where all aspects of schooling were explicitly designed through their structures, schedules, and regiments to be analogous to the industrial-age factory (Callahan, 1962). While the direct commitments to scientific management and managerialism have been replaced by theories that increasingly recognize schools as complex socio-ecological organizations, the field's foundations in scientific management are part of our DNA, representing a “set of perverse incentives that shape these roles and steer daily activities toward the managerial” (Cuban, 1988).

Given this historic foundation, Myran and Sutherland (2019b) argued that scientific management continues to dominate our field's outlooks, what some have called Neo-Taylorism (Au, 2011; Gronn, 1982), Managerialism (Gunter, 1997, 2009), or Neo-Managerialism (Terry, 1998). As such, the managerial design philosophy reduces the complex and reciprocal interactions between and among the learner and the socio-educational ecology to mere “strategism”, what Morozov (2013) called “technological solutionism”, that is the formalized, routine, and procedural dissemination of knowledge. This dominant cultural perspective has in turn shaped our thinking about the nature of learning and teaching, how we conceptualize and design schools, as well as our roles and responsibilities within them. These scientific management influenced organizational practices assume (1) knowledge is a collection of facts and procedures, (2) the goal of education is to disseminate these facts and procedures, (3) teachers' job is to transmit this knowledge to passive students, (4) that simpler facts proceed more complex ideas, and (5) success is achieved when students can demonstrate they have mastered these facts and procedures through testing (Sawyer, 2006b).

Analysis

Drawing from the above, I used the peer-reviewed and seminal literature on instructional leadership and leadership content knowledge as my source of data and conducted a systematic review of these literatures from a thinking with theory and theory building perspective. That is, I interrogated this literature looking for congruence and incongruence with the science of learning, identifying emergent perspectives on human agency and the social and reciprocal dynamics of learning, as well as identifying aspects of the literature that were theoretically and practically tied to managerial perspectives. I identified articles on these topics using key word searches in both Google Scholar and the Education Resources Information Center (ERIC) with permutations of *instructional leadership* and *leadership content knowledge*, followed references and citations as indicators of impact on the field, followed lines of reasoning to new articles, and actively sought out counter evidence to curtail a priori biases.

Once identified, I created an EndNote bibliography including PDFs of all articles. Next, I imported this bibliography along with all the PDFs into NVivo qualitative research software. Using Myran and Sutherland's (2019b) gestalt synthesis of the science of learning literature and managerial critique discussed above, through an iterative and reciprocal process, I read, coded, and annotated all of the articles, first through a rounds of open coding, followed by subsequent rounds of axial and selective coding to

develop a thematic structure. As my reading and coding revealed possible additional articles, I added those to my databased and integrated these new data into my workflow. The process of writing the manuscript itself proved to be part of the iterative and reciprocal nature of this work, offering a means of sense-making, and refinement of the final thematic structure, which is outlined below.

Findings

The resulting analysis highlighted four interdependent themes. They are, (1) an evolving transformation from a dominant focus on the management and supervision of learning to an increasingly student centered and instructional leadership orientation, (2) the emergent, yet indirect referencing of the principals of learning, (3) given the identified disjunctures between management and the science of learning, the leader's role in supporting learning continues to be somewhat ambiguous and as a result, a host of folk epistemologies have evolved that are antithetical to the science of learning. Finally, (4) there is a strong theme of the legacy of scientific management found throughout the literature reviewed which reveals important, yet under-identified incongruent theories of action that must be examined, understood, and overcome in order to meet the potential of this evolving focus on learning (see Fig. 1).

I conceptualized this thematic structure as interrelated, irreducible, and cyclical. Each theme provides the next the basis for understanding the larger model and together they work as a self-perpetuating and self-referential system. The overall model presents a struggle between an emergent or nascent turn from a prominent managerial theory of action to a learning focused theory of action grounded in an understanding of the reciprocal causation among the various actors within complex social-ecological systems. Within this struggle we see this nascent focus on learning influenced by, if not misshapen by the managerial traditions and associated historically habituated structures, norms, and assumptions that are fundamentally incongruent with the science of learning. Given the incongruent nature of the theories of action found in the last theme in the model, these disjunctures between the science of learning and the legacy of scientific management perpetuate the struggle between the potential of instructional and content leadership and the managerial "conduits of pressure" (Mintrop and Trujillo, 2005; Mintrop, 2004) experienced by school leaders. In turn, this dynamic helps to maintain the ambiguity of the principal's role in supporting learning, reifies folk epistemologies, perpetuates the legacy of scientific management, and reinforces the incongruent theories of action. Each of these interrelated themes, along with examples from the literature reviewed are discussed in greater detail in the subsequent sections of the chapter.

From management to learning: the evolution of instructional leadership and leadership content knowledge

A prominent theme that emerged through my analysis was how educational leadership has been in a period of transition from a primary focus on the management and supervision of schooling to a more learner-centered and pedagogical orientation. This

Fig. 1 Self-replicating incongruent theories of action.

literature paints a picture of a growing interest in the role school leaders play in developing, supporting, and maintaining a climate of high-quality teaching and learning. Central to this theme was a clear thread that ran through this literature that contrasted the leadership characteristics and capabilities of supporting teacher quality and student learning from those associated with the management and oversight of a school or school system. Relatedly, these management responsibilities tended to be framed as a fundamental barrier to the implementation and fidelity of instructional leadership. As scholars and practitioners have grappled with the transitions between management and instruction there has been a tendency to bifurcate the management of a school or school system from instructional leadership, what [Shen \(2020\)](#) called the bifurcated fault line between the school/principal and the teacher/classroom level.

From management to learning

Most scholars attribute the development of the construct of instructional leadership to effective schools research, generally attributing this to scholars such as [Edmonds \(1979\)](#), [Purkey and Smith \(1983\)](#), and [Weber \(1971\)](#), and the increasing interest in the role that principals and other school leaders play in impacting student learning. [Weber's \(1971\)](#) influential research actively differentiated the focus from the prior work of Coleman, Jensen and other researchers that made assumptions that the low achievement of poor children was primarily the result of "inherent disabilities characterizing the poor" ([Edmonds, 1979](#)). Building from Weber's work, [Edmonds' \(1979\)](#) seminal research, *Effective Schools for the Urban Poor*, which summarized a number of other studies, emphasized that effective schools have strong administrative leadership, are instructionally effective, promote a school's atmosphere that is orderly and safe without being too rigid or oppressive, prioritize learning over other school activities, and frequent monitoring. Just as importantly, Edmonds was emphatic that student's background was not a determinant in their ability to learn and emphasized that student failure was in part a school failure.

At the same time, this emergent shift from a primary focus on management to one of learning was nonetheless notably shaped by the prevailing scientific management design philosophy. Even with the increasing evidence of the limitations of scientific management as an appropriate frame of reference for education, because the massive bureaucracies that support public education had been well established prior to a science of learning ([Sawyer, 2006a](#)), the underlying organizational norms, values, assumptions, and practices were well entrenched ([Myran and Sutherland, 2019b](#)). It could be argued that the tenets of the effective schools movement were shaped by the same positivist frameworks that well may have been a key source of the dissatisfaction with traditional managerial models, and as such they ignored or overlooked the multidimensional social and cultural intricacies that managerial and managerial design philosophies are not effective at addressing ([Dantley, 1990](#)). The lists of factors of essential schools were "grafted" onto schools, a graft that rarely took hold due to competing ideologies ([Cuban, 1998](#)) and the well-established managerial perspectives.

In the more contemporary instructional leadership literature, the field continues to struggle with the transition from management to learning, what some have referred to as a shift from behaviorism to constructivism ([Nelson and Sassi, 2000](#)), or what [Robinson \(2006\)](#) referred to as putting education back into educational leadership. This literature offers a rich view on how scholars have grappled with the tensions between the dissatisfaction with the prominent managerial paradigm, the need to shift more effectively to learning centered models of leadership and the limitations of the historic grounding in managerialism. Here we can see an increasing emphasis that shifts from broad school level factors such as promoting high expectations, facilitating a positive school climate, decentralizing decision-making, to more teacher, classroom and student focused skills such as observing and assessing instruction, identifying instructional supports for struggling students, giving feedback to teachers, evaluating curricular materials, and engaging in meaningful, sustained instructionally focused conversations with teachers, and building and leveraging their knowledge of the content being taught to sharpen their focus on all of the above ([Carver, 2012](#); [Quebec Fuentes and Jimerson, 2020](#); [Steele et al., 2015](#); [Stein and Nelson, 2003](#); [Gracjewski et al., 2009](#); [Hallinger, 2010](#); [Robinson, 2010](#)).

Leadership content knowledge: refining the focus on learning

As discussed above, the instructional leadership literature highlights an evolving shift from managerial to learning perspectives and an increased focus on those elements that are closer to the source of learning, that is the classroom interactions between and among students and teachers. Within this increasingly more nuanced and learning-centered exploration, leadership content knowledge offers a refining focus on learning, helping to fill in gaps between the broad construct of instructional leadership and the nuanced skills, knowledge, and behaviors that may serve to scaffold and support learning at the actual source of learning. In this way, leadership content knowledge may serve as a means of sharpening the lens through which school leaders look at, understand, and support instruction and learning ([Stein and Nelson, 2003](#); [Steele et al., 2015](#)).

Just as importantly, as the field has moved from broad school level factors, to more teacher and classroom factors, there has also been a growing recognition of the importance of school leaders knowledge of the nature of student engagement ([Nelson and Sassi, 2000](#); [Steele et al., 2015](#)), a further indication of the push for more fully developed learning focused theories of action that can replace traditional managerial orientations. Just as the development of pedagogical content knowledge prompted new insights about teaching, leadership content knowledge offers a similar means of pushing the field further toward a more learning focused construct ([Stein and Nelson, 2003](#)). Taken together, leadership content knowledge is considered a co-defined construct, that is the blending of instructional leadership, content knowledge, and pedagogy ([Stein and Nelson, 2003](#)).

However, outside of the knowledge of the content itself, and the anecdotal and craft knowledge that comes with experience, there is a notable challenge in identifying the source of this pedagogical understanding. How do school leaders or teachers identify modes of inquiry best suited for a particular discipline, effective curriculum, and evidence-based practice in the absence of a robust

foundation in, and understanding of the science of learning? As Myran and Sutherland (2019b) point out, under the design principles of scientific management and managerialism, there is an assumption of a linear, cause and effect impact of leadership on the school climate, teachers and consequentially, student learning. The assumption is that the influence of leaders is primarily at the organizational and school level, and the evidence about the impacts on student learning begins at the school level and is traced back to through the levels of this hierarchy. As a result, the distance between school level factors and the more nuanced and bi-directional interactions between students, teachers, and the school climate, abstracts the students' active and reciprocal role and may risk defaulting to assumptions about students as the products of these school-level mechanisms and leadership practices. As Stein and Nelson (2003) note, "Without knowledge that connects subject matter, learning, and teaching to acts of leadership, leadership floats disconnected from the very processes it is designed to govern" (p. 446). This is a critical point, and I would push this logic further and suggest that without a foundation in the science of learning, leadership will continue to be disconnected from that which it seeks to have influence over.

An emergent focus on learning

Closely related to the theme of the evolving transformation from management to learning, I noted an emergent, yet indirect referencing of the principals of learning. Within this emergent shift from management to instructional leadership, we can also see a pattern that begins to hint at science of learning perspectives, moving from broad school level factors to classroom and teacher factors, and finally to more serious considerations for student level cognitive and motivational factors. Within this theme I identified a pattern of evidence that hinted at theories of learning, a push to move the field beyond generic conceptions of learning focused leadership, as well as a push to ground the field more fully in the core business of education, that is learning. Taken together these first two themes could be considered as an indication within the field of a *learning turn*, a paradigm shift from a managerial outlook about learning to one informed by the science of learning.

Hinting at theories of learning

Beyond the general shift from managerial to learning foci, I also observed an emergent emphasis on a more learner and person-centered framing of teaching and learning. Here the literature emphasized that instructional leadership should be fundamentally grounded in the core purpose of schooling (Mullen and Schunk, 2010), establishing a greater understanding of student and teacher thinking as foregrounding to the work of educational leadership (Steele et al., 2015), school leaders seeing themselves as learners (McGhee and Lew, 2007) and recognizing the complex and dynamic nature of learning and school organizations (Brazier and Bauer, 2013). More specifically, these person and learning-centered frameworks highlighted a participatory (Mullen and Schunk, 2010), bidirectional and reciprocal outlook about the nature of learning (Steele et al., 2015; Stein and Nelson, 2003; Mullen and Schunk, 2010), the importance of collaboration, discourse, and dialogue (Robinson et al., 2008; Quebec Fuentes and Jimerson, 2020; Nelson and Sassi, 2000; Brazier and Bauer, 2013; Mullen and Schunk, 2010), student, teacher, and leader engagement, (Graczewski et al., 2009; Nelson and Sassi, 2000), and intellectual risk taking (Nelson and Sassi, 2000).

In this way, leadership content knowledge provides the grounding for the core function of schooling, moving beyond what effective leaders "do," to how they think about, internalize, and understand what they do (Stein and Nelson, 2003) in reciprocal interactions with others in the learning context and in relationship to the core purpose of schooling. Stein and Nelson emphasized that learning is facilitated by what they described as "asymmetries in expertise" and expertise within the larger school organization shifts among different individuals or groups based on the nature of the work at hand. As such, they highlight that the job of school leaders is to organize and facilitate such that these knowledge resources can interact in productive ways; that is not transmitting knowledge, but discovering the learning needs of the organization, creating spaces for engagement, incentivizing learning, and assuring there are appropriate learning resources (Stein and Nelson, 2003). Instead of focusing on how students internalize content, school leadership should be more focused on how students think and engage with others, a shift that Brazier and Bauer's (2013) view as "seismic", that is, thinking about learning as the consumption of knowledge "misses the point. The action is in how students know in relation to the problems at hand and to their fellow students" (p. 3).

Emphasizing building leadership orientations around the core purpose of learning, Mullen and Schunk (2010) have emphasized that when school leaders engage in instructional leadership that is participatory in nature, collaborative, and reciprocal, authentic, involves co-learning, deep cultural exchange, shared power and control, and active engagement among critically reflexive participants, they are able to foster meaningful improvements in the instructional capacity of the school. Leadership content knowledge helps to connect the core function of schooling, learning, and teaching to leadership – helping to move beyond generic perspectives on school leadership. Without this, the work of school leadership is disconnected from the very processes it is designed to govern (Carver, 2012).

Similarly, strong content knowledge has been shown to help school leaders foreground student thinking, and student/teacher interactions, shifting their frame of reference from surface-level characteristics of effective teaching to the more complex and dynamic aspects of student thinking and student/teacher engagement (Steele et al., 2015), suggesting a nascent understanding of the reciprocal and bidirectional nature of learning. Representing a related shift in orientation, as McGhee and Lew (2007) have pointed out, school leaders who model intellectual curiosity, set learning goals, and see themselves as lifelong learners, proactively build a culture of continuous learning, work at fostering and sustaining a shared vision of commitment to student success, and more effectively foster a community of learners. However, as powerful as this potential seismic learning turn may be, few of these observations directly referenced the learning and psychological sciences, which offers significant theoretical substantiation for this turn.

Ambiguity, folk epistemologies and social consensus

Even with the evolution of this learning turn, my review of these related literatures suggests that there remain ambiguities about the principal's role in supporting learning. Given the tendency within the larger field to default to scientific management/managerial frames of reference (Au, 2011; Gronn, 1982; Gunter, 1997; Myran and Sutherland, 2019b; Donaldson and Allen-Handy, 2020) and the absence of well-defined applied and theoretical definitions of learning (Myran and Sutherland, 2019b), educators have been left to fill in these gaps based on their own experiences as learners, and their training and professional experience (Printy et al., 2008). This in turn has the effect of amplifying well-established and historically rooted assumptions about leadership, teaching, and learning, and privileging social consensus over a science of learning in the framing of instructionally focused leadership.

Through my analysis, I found that the ambiguity of the school leaders' role in supporting learning may tend to reify *folk epistemologies*. That is, our commonsense, everyday, or, intuitive conceptions of knowledge and knowing. (Gerken, 2020; Hardy-Vallée and Dubreuil, 2010), which are derived from experience, the contextual utility of a knowledge claim, and the subsequent social consensus. The absence of an empirical grounding in the science of learning and the implicit folk epistemologies tend to misrepresent, misunderstand, overlook, or disregard the student's active and deliberate agency and their reciprocal engagement in the socio-ecological learning context, sometimes treating students as the product of educational management.

Pushing against the constraining features of the prominent managerial paradigm, leadership content knowledge scholars (Stein and Nelson, 2003) sought to emphasize a type of connoisseurship and educational criticism (Brazier and Bauer, 2013) that would allow an administrator to know strong instruction when they see it; leveraging what they know about the content of a particular subject to build these capabilities. In this way, subject matter knowledge, pedagogy, and leadership are considered the basis of leadership content knowledge (Stein and D'Amico, 2000; Stein and Nelson, 2003). While this pushes against the limitations of the prominent managerial norms and begins to bring expertise of teaching, content knowledge and pedagogy to the center of leadership theory, it nonetheless leaves an empirical understanding about learning, the very point of these leadership constructs, undefined.

Framing instructional leadership and learning through the lens of management

In the absence of clearly defined theoretical and operational definitions of learning, I further noted a tendency for this literature to conceptualize learning through the prominent managerial lens. Across the reviewed literature I noted an underlying theme of viewing instructional leadership as an additional responsibility added on top of the foundational managerial responsibilities. Here the literature represents the management of the school as the floor, with new school leaders learning the skills of management that allows them to fulfill the basic needs of the school, upon which instructional leadership is grounded (Brazier and Bauer, 2013; Grissom and Loeb, 2011). Similarly, school leaders' management and instructional responsibilities have often been framed in contradictory ways (Brazier and Bauer, 2013; Bridges, 1967; Hallinger, 2011).

Grissom and Loeb (2011) note that one of the challenges for the broad and ambiguous construct of instructional leadership is "distilling which behaviors count as instructional leadership and which do not" (p. 433). This highlights the assumptions of the hierarchical, linear, and recursive impact of leadership on each subsequent and subordinate level of the organization. Here we see language such as, how some leadership actions "yield positive outcomes", which masks the reciprocal role of not only the students themselves, but those in roles subordinate to leadership. Robinson (2006) highlights that educational leaders have been historically assessed on their effectiveness as managers of the fiscal, organizational, and political climate of their building, that is setting the stage or creating the conditions in which teachers can carry out the educational mission. More recently however, there is a growing expectation that school leaders will take charge of the instructional climate as well, directly influencing student learning through their own enhanced knowledge of content and pedagogy and instructional leadership behaviors (Robinson, 2006). The underlying assumption being that through such linear and recursive structures leadership would have a direct and in-direct impact on student learning. Within this framing, many scholars have sought to understand the impact of leadership on learning and how the two are linked, generally assuming a hierarchical causal chain between leadership and student outcomes (e.g., Graczewski et al., 2009; Leithwood and Seashore-Louis, 2011; Olsen, 2006; Robinson, 2010; Steele et al., 2015).

Analysing this observation through a science of learning lens I noted a concerning disjuncture between the assumption of this causal chain and the gestalt synthesis of the science of learning (e.g., Alexander et al., 2009; Myran and Sutherland, 2019b). Some 70 years of post-cognitive revolution research makes it abundantly clear that learning is not a one-way causal dynamic between educators and learners; such a view significantly misrepresents that agency of the student, their introspective capabilities, motivations, and just as importantly, the bi-directional impact of their interactions within the complex social-ecological context of schools and classrooms. Because, "we are both products and producers of our own learning environments" (Myran and Sutherland, 2019b), the determinants of student learning can't be understood outside of what Bandura (1989) described as the causal contribution learners make to their own learning within a system of triadic reciprocal causation. Critically, as discussed earlier in the chapter, Bandura (1989), emphasized that any account of the factors that shape learning must include these reciprocal factors – that is the learners' own agency, their cognitive, affective, and other personal factors in bidirectional interactions with the learning environment, which collectively operate as interacting determinants of learning. As such, the traditional conception of a causal chain between leadership, teachers, and student learning disregards or overlooks the student's own self-generating influences on both the process and outcome of engagement in the learning environment.

Illustrating these disjunctures, one of the quandaries in the leadership content knowledge literature is how a principal or other instructional leaders could practically have substantive enough knowledge about every content area taught in the school to be an effective instructional leader with all teachers and all classrooms (Robinson, 2006; Stein and Nelson, 2003). Two solutions to this

challenge are offered in the literature. The first is through the delegation or distribution of instructional leadership (e.g., Spillane et al., 2003, 2004), and the second is through the concept Stein and Nelson (2003) refer to as *post-holing*, that is grounding a broader understanding of effective instruction in a depth of knowledge in a single subject area. Interestingly both solutions appear to be anchored to a management foundation and as such may overlook or disregard the theories and science of learning that I would argue should undergird the leadership content knowledge construct. This may represent a disjuncture between the foundation in management and the growing turn from this foundation to learning. Without an understanding about the nature of learning itself, in-depth knowledge of a given content area and the pedagogy unique to a given content area is insufficient to build broad and flexible understandings about what effective instruction looks like and how to provide meaningful instructional support to teachers. Here we can see the limitations of managerial outlooks as the foundation that leadership content knowledge is built on.

Linear, hierarchical, and cause and effect assumptions about learning

Across this literature I found a thematic pattern that framed learning within a largely linear, hierarchical, and cause and effect frame of reference. That is, discourse that frames the pressures of accountability as a management task that requires instructional leadership to help improve teaching, which in turn results in producing higher scores on benchmark tests and summative assessments. The assumption here is that principals are responsible for ensuring that teachers increase their knowledge and that this increased teacher knowledge will lead to changes in instruction and produce higher student achievement (Graczewski et al., 2009). In essence, there is a clearly defined linear, hierarchical, and cause and effect assumption about how improvements in learning are achieved, entirely leaving out the agency of the individual actors and the reciprocal role they play in what is in fact a complex and dynamic interplay between the individuals, their agency, motivations, introspective capabilities, and the complex socio-cultural school context.

The language used across the literature often suggested a strong leaning toward this linear and power-centric conceptualization about how improvements in learning take place. Here I found statements to the effect of, the role of schools in achieving student gains, identifying the determinants of student performance, linking improvements in teacher performance to student achievement, how a principals' modeling behaviors can impact teacher quality and student learning, principals as managers that assure that teachers are "delivering" mandated curriculum, and how support is delivered to struggling students. These types of statements seem to reveal a prevailing undertone of a recursive conceptualization of the role school leaders play in student learning, that is a *telescoping* (Printy et al., 2008) phenomenon where at each subsequent level of the organization the responsibility encompasses the learning needs of everyone at the each of the subordinate levels, requiring a superintendent, for example to understand, manage and control the learning needs of principals, teachers, and students. Here leaders become the teachers of the other educators who are subordinate to them, supervising, orchestrating the learning environment, implementing incentives for learning, assuring adequate resources to support learning, and assuming the responsibility for their learning (Printy et al., 2008). These conceptualizations are often represented with student learning outcomes as the dependent variable of the recursive impact of a linear and hierarchical set of independent variables (e.g., Bossert et al., 1982; Dumay et al., 2013).

Hinting at reciprocal causation

Even within the prevailing recursive framing, I also found counterexamples which are closely related to the theme of an emergent focus on learning discussed earlier. While much of the language across the reviewed literature reveals the linear, hierarchical, and cause and effect impact of leadership on student learning, that is the recursive and accumulative impact of leadership at each subordinate level of the organization, there were also counterexamples that present a more reciprocal and human agency supportive framing of the role of instructional leaders. Here I found language to the effect of honoring the professionalism of teachers, engaging in mutually beneficial discussions around instruction, principals and other school leadership learning alongside teachers, collaboration, student attitudes, self-concept, behavior, attitudes of peers, and participative leadership (e.g., Bell et al., 2003; Quebec Fuentes and Jimerson, 2020; Robinson, 2006; Robinson et al., 2008).

More pointedly, a few scholars have challenged the direct and mediated effects models of school leaders' impact on student learning, arguing these models do not capture the complex and dynamic interactions between and among the variables involved in these models (e.g., Hallinger and Heck, 2010, 2011; Oude Groote Beverborg et al., 2020; Shen et al., 2019; Shen, 2020). For example, Hallinger and Heck (2010, 2011) offer a reciprocal-effects model, that is a non-recursive conceptualization of the dynamic and changing relationships among the relevant variables over time. Here leadership is viewed not as a unitary and independent influence on learning, but one that both gives shape to, and is in return shaped by the other variables in the model. In other words, leadership and the other variables that may influence learning have both a cause and an effect on each other. This echoes aspects of Bandura's social learning theory (1979, 1985) and reciprocal determinism model (1978, 1984) from some 40 years ago. This may represent an evolution of how knowledge and learning are conceptualized; from a recursive and reductionist direct effect model, to mediated effects models that recognize that simple, direct, cause and effect framing oversimplifies the confluence of complex factors that come together in the learning setting, to a reciprocal model that is better supported within the science of learning (e.g., Bandura, 1978, 1979, 1984, 1985) systems thinking (e.g., Bronfenbrenner, 1992; Mingers, 1997) and complexity theories (e.g., Kaplan and Garner, 2017).

However, while these models begin to reconceptualize the complex and reciprocal interactions among the variables that may influence learning, they do not consider the active and reciprocal role of the students themselves in shaping the learning environment and their own learning outcomes. The reciprocal dynamics between the learner's prior knowledge, introspective capabilities, self-concept, and the socio-ecological educational setting are only hinted at. As such, these models do not capture the fuller reciprocal dynamics the science of learning has made an increasingly clear argument for (Myran and Sutherland, 2019b). This may

suggest an undercurrent within the field of a nascent intuition about the reciprocal dynamics among all the actors within the school setting, including the students themselves. However, without a robust discourse on these disjunctures, and an appropriate reconceptualization of instructional leadership and other leadership models, this emergent focus on learning may not realize its potential.

The legacy of scientific management: incongruent theories of action

As we can see in the discussion of the previous themes, even with this ongoing transformation there remain notable concerns about these disjunctures. The aspiration of instructional leadership, the sedimented histories of the field that tend to frame learning as linear, recursive, and the act of delivering and receiving content, and the science of learning represent incongruent theories of action and design philosophies. Donaldson and Allen-Handy (2020) described these managerial traditions as drawing from a *transfer/acquisition metaphor*, conceptualizing education as something that is *provided*, or *delivered*.

Despite a long history of school reform efforts in the United States and beyond, sustained implementation of research-based practices with fidelity is limited and sporadic (Brazier and Bauer, 2013; Cuban, 1984, 1990, 2013; Deschenes et al., 2001; Tyack and Cuban, 1995). Instructional leadership and leadership content knowledge models have not escaped this phenomenon. I would argue, that an under identified aspect of the lack of fidelity and sustained implementation is the legacy of scientific management and the incongruent theories of action between this foundation and the science of learning.

Discussion and implications

Taken together, I agree with Brazier and Bauer's (2013) view that educational leadership's shift in conceptualizing how students internalize content to how they think and engage with others is "seismic". The question remains however, how we make this seismic shift. The research on instructional leadership and leadership content knowledge offers both optimism and caution. Some have framed leadership as second only to classroom teaching as an influence on student learning (Leithwood et al., 2004; Leithwood and Seashore-Louis, 2011; Louis et al., 2010) and that this influence is achieved through leaderships' impact on the school organization and culture and teachers' classroom practices (Day et al., 2016; Witziers et al., 2003). Others have expressed caution, voicing concerns about the lack of precise definitions of instructional leadership (McGhee and Lew, 2007; Brazier and Bauer, 2013; Neumerski, 2013), which in turn make its implementation unobtainable (Brazier and Bauer, 2013; Rigby, 2014; Salo et al., 2015), and the contradictory nature of school management and instructional leadership responsibilities (McGhee and Lew, 2007).

Given the exploration of these interrelated themes, I suggest that what is missing is a grounding in the science of learning, which would help to replace assumptions rooted in theories of action more closely related to efficiency, uniformity, and productivity than theories of learning. On the one hand, it is difficult to argue against the appeal of efficiency and productivity; given limited financial, time, and human resources, why wouldn't educators be drawn to the appeal of relatively simple linear, hierarchical, cause and effect solutions. However, as a primary theory of action these managerial norms rest on shaky ground, potentially misrepresenting and oversimplifying the nature of learning itself, and therefore misguiding what forms of instruction and organizational support best facilitate substantive, lasting, and transferable learning. In this way, one of the implications of this analysis is that beyond the co-defined construct of instructional leadership, content knowledge and pedagogy, the field needs to continue following this evolution of learner and student-centered constructs and reframe instructional leadership around the science of learning.

I make the argument that what is needed is a reconceptualization of instructional leadership through a science of learning lens that disrupts the self-replicating incongruent theories of action outlined in Fig. 1. By introducing the science of learning as the foundational theory of action, the emergent focus on learning present in the literature to date can overcome the ambiguity, folk epistemologies, and social consensus, that may serve to constrain the emergent learning turn evident in the literature. With the introduction of this element to the model, the legacy of scientific management is disrupted, ambiguity and folk epistemologies are replaced with empirical evidence about learning, which in turn help to reveal the hidden, obscured, or taken for granted scientific management influenced perspectives on learning; supporting new insights that offers alternative explanations and counter theories that can build toward theories of leadership congruent with the science of learning (see Fig. 2).

Navigating the learning turn

The *learning turn* discussed here invites us to engage in discourse and action that is more substantively grounded in the science of learning. Such a reconceptualization of instructional leadership builds on the nascent focus on learning and offers a means to "escape the gravitational pull of the recalcitrant effects of scientific management in its past and current forms" (Myran and Sutherland, 2019b).

However, the sedimented histories and habituated norms established prior to the systematic study of learning presents a notable barrier. There is something seductive about hierarchical solutions, they offer uniform strategies that can be easily written into policy, implemented, overseen, and managed. However, given the complex nature of learning, such *solutionism* (Morozov, 2013) is incongruent with what we have known about the complex, reciprocal, dynamic and social-cultural nature of learning since the cognitive revolution some 70 years ago. Because our field does not offer any kind of theoretical or working definition of learning; often

Fig. 2 Congruent theories of action which support iterations of improvement.

substituting performance as a proxy for learning, our ability to continue refining and strengthening the potential of instructional leadership is significantly limited, if not unattainable. It may be that we've reach the practical and functional limitations of a field that has yet to define its primary objective. In this respect, without reframing instructional leadership around the science of learning, the learning turn may merely leave us right where we've been for the past 100 years, attempting to cause and predict something that defies simple linear, hierarchical, cause and effect conceptualizations.

Introduction

Across the United States and other nation states (e.g. UK, Canada, Australia, New Zealand), we can observe similar policy trends toward externalized evaluations, curriculum centralization, and evidence-based programs as well as demographic trends toward increasingly diverse student groups due to global population migrations and internal demographic shifts. Indeed, the United States is projected to be a majority minority nation state by 2050 (Hoy and Hoy, 2012). Thus, the educational leadership literature focused on curriculum, instruction, and learning is now complicated with tensions between diversity and commonality amid the Covid 19 pandemic and pressures for equity. The purpose of this chapter is to review extant literature on leadership for learning in relation to education theory and changing contexts. Consonant with this purpose, the chapter is organized into sections that consider changing demographics and policies that impact educational leadership, the strengths, and limitations of extant leadership literature as well as literature on education theorizing to enhance understandings of leadership for education and learning, and implications for leadership practice and preparation in light of changing contexts.

Changing student demographics

Demographics are changing due to global population migrations and internal demographic shifts. Currently, White people constitute the majority of the US population (62%); however, the percentage is expected to fall below 50% by 2050 with Hispanic populations to experience the largest increase (Colby and Ortman, 2015; Hoy and Hoy, 2012). As of the writing of this chapter, the combined nonwhite population—blacks, Hispanics, Asians, persons identifying as multiracial, and other races—comprized the dominant share of the under-age populations (50.1% compared with 49.8% in 2017), with Hispanics accounting for more than a quarter of this youth demographic. Diversity ranges by state, but the trend is spreading across the United States. These population changes are due to global population migrations as well as internal demographic shifts, including a decline in young whites. The decline in the number of white children under age 15 has declined over the 2010–2018 period by 2.2 million, continuing a trend toward diversity already observed in the first decade of the century (Brookings Institute, 2020).

Cultural diversity brings multiple experiences, values, and views of knowledge to educational institutions and the academics within them to schools. Since the 1960s, there has been a significant increase in the number and diversity of immigrants coming to the US, and the number has steadily increased over decades. The U.S. Census Bureau notes that the increasing number of international migrants will make the country “a ‘plurality’ of racial and ethnic groups” (Colby and Ortman, 2015, p. 9). For example, the Hispanic population has grown from 6.5% of the US population in 1980 to 17.6% in 2015 (Pew Research Center, 2015) while the Two or More Races population is projected to grow by 225% between 2014 and 2060 (Colby and Ortman, 2015). At the same time, policies are changing with trends toward centralization and an emphasis on evidence-based programs that “work” for all students (Ylimaki et al., 2021; Ylimaki and Brunderman, 2022).

Policy trends

Historically, in the US, policies under both Republican and Democratic administrations have supported the need for externalized evaluations (standardized assessment data) to hold schools and leaders accountable. Additionally, since 2002, there has been a drastic rise in the call for education research funded by the Office of Educational Research and Improvement (OERI) that addresses causal questions using random assignment designs [prior funding for randomized controlled trials represented 5% of federal funding for education research compared to 75% by 2002 (Morrison, 2012)]. Currently, funding applications for

U.S. Department of Education grants must include research designs that are based upon prior studies with “strong evidence” (explicitly defined by large-scale quantitative studies with randomized controlled trials or quasi-experimental designs). In the international arena, multinational organizations (the Organization for Economic Co-operation and Development (OECD) and the World Bank) have also made evidence-based policymaking a priority, both in their own work as well as for their members (Wiseman, 2010).

Globally, we can also observe a policy convergence toward such compliance requirements, curriculum centralization and rankings for school quality and performance (Pilton, 2009; Steiner-Khamsi, 2006). As Pilton (2009) explained, there are several ways that policy convergence contributes to evidence-based policies, curriculum centralization, and comparisons or rankings of schools, states, and nations. One way is through imposition. Imposition is typically a result of political demand or pressure (e.g. Organization for Economic Cooperation and Development/OECD agenda, World Bank) and requires compliance with international policy or institutional arrangements. There is no legal obligation to participate in the Program for International Student Assessment (PISA) with OECD; however, at OECD urging, member nations comply with evidence-based policies. Further, as Meyer (1977) and other institutional theorists would argue, when OECD identifies nation states with “high performing” schools, others emulate these practices (e.g. centralized curriculum) as they are legitimized. Such evidence-based policy convergence also contributed to research trends in funding applications, particularly research methods that are considered “scientific” and measure what works to improve schools.

New bureaucracies have also emerged in relation to neoliberal policies, all of which demand strong leaders who can mediate among many different (and sometimes conflicting) policies, diverse student needs, and democratic education values. Further, school leaders now must work collaboratively within and between governance systems or levels, balancing evidence-based values, and the humanistic values of education for increasingly diverse students.

In many nations, including the United States, education is primarily the responsibility of individual states; there are a variety of external evaluations (state tests) given in different states and sometimes in different districts. For example, in the state of Arizona, students currently take the AZMerit test of knowledge and skills. There is no longer a graduation exam in Arizona, but some school districts additionally require all students to take the ACT exam. In another US state of South Carolina, beginning in grade 3, students take the State Palmetto Assessment of State Standards (SCPASS) in English/Language Arts, Mathematics, Science and Social Studies. The High School Assessment Program (HSAP) is first administered in grade 10, and South Carolina high school students must pass this test in order to receive a high school diploma. National tests, such as the National Assessment of Educational Progress (NAEP), provide nationally representative achievement information in core subjects. International assessments that are widely taken in many countries (e.g. PISA, TIMSS) have often driven national policy decisions toward an increased use of tests as evidence of school quality or success. Although there is a range in the extent to which the results of these assessments directly affect individual students, the average student scores for schools, districts, states, and nations as a whole are widely accepted indicators of educational quality and have a major impact on educational policymaking (LeTendre et al., 2001).

The degree of equity and equality attained in an educational system is another reason frequently cited for assessing the performance of students and schools through externalized evaluations. By seeing who performs highly and who does not, it is possible for teachers, administrators, and policymakers to determine disparities among individual students, classrooms, and schools (Heilig and Darling-Hammond, 2008; Darling-Hammond, 2010). The logic behind using evidence to demonstrate equality suggests that policymakers can design policies and laws to close achievement gaps. For example, Arizona, like many other states, has a wide achievement gap between students from various social and economic groups. The state test (currently AZMerit) shows that this gap exists and the extent to which it exists in particular content areas. Arizona politicians have used this evidence to reward high performing schools and to punish low performing schools. Analysis of standardized achievement scores clearly falls along socioeconomic lines across the nation (Perry et al., 2010; Baker and Johnston, 2010; Cunningham and Sanzo, 2002) and has contributed to the rise of charter schools, vouchers, and public mechanisms to ensure greater equality among schools. Thus, politicians—with evidence from state tests—have passed legislation and policy targeting underperforming schools, requiring shifts in the curricular and classroom focus in order to close those achievement gaps. Under NCLB, if disaggregated data for each student subgroup (i.e. race, gender, language proficiency, etc.) do not demonstrate adequate yearly progress, then the U.S. Department of Education may withhold federal funding from the state or district within the state (McDermott and Jensen, 2005). In 2015, the reauthorization of NCLB resulted in the Every Student Succeeds Act (ESSA), which returned some control to states to determine their goals. Students are still required to be tested annually in grades 3 through high school, but the federal government removed many of the prescriptive pieces of the legislation (U.S. Department of Education, 2016). However, Arizona (as in many states) has not changed state legislation to reflect the greater flexibility of ESSA. It should also be noted that in Arizona, the state test was designed to have both criterion-references components and others that served as norm-referenced items by testing standards at, above, and below the grade level for which the test was designed.

Historically, federal and many state policy makers have attempted to address inequities through legislation. For example, the Coleman Report from the 1960s suggested that family and peer influences, not school resources, are the most important determinants of student performance (Baker and LeTendre, 2005). The Coleman Report was conducted in the wake of the court case *Brown vs. Board of Education of Topeka* that ruled that racial segregation of children in US public schools was unconstitutional. “Evidence” from the landmark court decision and the latter Coleman Report changed the course of equity-driven policy making in the United States and in many other countries. The Coleman Report was part of President Johnson’s strategy in the Great Society program to level the playing field by identifying evidence of inequality in schooling. Coleman surveyed over 560,000 students across the

US, a methodology partly due to the fact that the system was highly decentralized. And while recent externalized evaluation and curriculum policies have shifted toward centralization (e.g. Common Core curriculum), administration of education in the US remains state based. During the time of the Coleman Report, Johnson and other policymakers thought they could address inequality with additional resources for low-socioeconomic schools as a strategy for improvement. However, while they found unequal resources available according to class and race, Coleman's team found evidence that some equity indicators like resources did not predict achievement. Variations in family background and outside-of-school environment affected achievement at least as much as variations in school resources and quality. In other words, some policy impacts cannot be controlled by policymakers. Closely related, Mexican American parents successfully sued school districts in California (Roberto Alvarez vs. the Board of Trustees of the Lemon Grove School District, 1931, and Mendez vs. [Aguirre et al., 2014](#)), both of which attempted to segregate Spanish-speaking Mexican American students in inferior "Americanization" schools.

The 1968 passage of the Bilingual Education Act (Title VII of the Elementary and Secondary Education Act) provided federal protections for culturally and linguistically diverse students. The Bilingual Education Act built from the *Brown v. Board of Education* case and the civil rights movement and promoted instruction that was both in a student's native language and culturally responsive. The act was far reaching, but it (and related state policies) remains at tension with the need to educate students in a common language and other common understandings and civic dispositions that create a nation state. Thus, today's school leadership teams must balance tensions between recent shifts toward curriculum centralization in the Common Core (and state versions thereof), related externalized evaluation policies designed to measure student performance, pressures to use evidence-based instructional programs and the needs of increasingly culturally diverse student demographics.

US policy makers control school funding; at state and national levels, test results are increasingly tied to funding, with the most recent policy wave beginning with the No Child Left Behind Act and its requirement for schools to make adequate yearly progress. Because the U.S. Department of Education has the responsibility for evaluating schools' and states' performance, it can and does use test performance as evidence and a means to control the curriculum schools adopt, the content teachers teach and other components of schooling ([Wiseman, 2010](#)). Since the No Child Left Behind Act, schools identified as not making Adequate Yearly Progress (AYP) over a series of years have been in danger of losing federal funding, and as such this has become vital policymaking evidence for school systems in every state. Some would argue that policymakers have opted toward evidence-based approaches over which they have control. Thus, leaders must implement policies aimed at commonality and also lead curriculum and instruction for increasingly diverse students in schools.

Studies of leadership for learning: strengths and limitations for changing contexts

In this section, I consider mainstream studies of leadership focused on learning in relation to the changing contexts reviewed above. More specifically, I primarily analyze literature on instructional leadership and leadership for social justice with aims for school and societal change respectively. In so doing, I argue that a philosophical approach grounded in the dignity of practice in addition to an analytical approach from empirical research may support leaders to balance and mediate tensions as they educate for an increasingly diverse humanity.

Mainstream leadership literature frequently either focuses on effective organizational theory-grounded approaches, programs and strategies that contribute indirectly to student learning outcomes (Day, 2005, 2007; [Hallinger, 2005](#); [Leithwood and Jantzi, 2005](#); [Marzano et al., 2005](#)). Or critical theory informed approaches that emphasize equity and social justice through equitable student learning outcomes, an increased social consciousness, culturally responsive practices, and community relationships (e.g.). In the following two sub-sections, I consider strengths and limitations of these leadership strands and suggest a further grounding in education and pedagogy as well as organizational and critical social theories to inform future directions for leadership amid the contemporary context and beyond.

Instructional leadership and the role of the principal

In empirical literature, the term *instructional leadership* emerged from the effective schools' research on "outlier schools," that is, those schools that effectively educated children from low socioeconomic (SES) backgrounds (e.g. [Berman and McLaughlin, 1976](#); [Edmonds, 1979](#); [Hallinger and Murphy, 1986](#); [Louis and Miles, 1990](#)). Following this same tradition, conducted a large-scale survey of principals and other educators and identified four leadership tasks or functions that distinguish high-achieving from low-achieving schools. [Hallinger and Murphy \(1986\)](#) constructed an "instructional" leadership model from earlier effective schools research ([Edmonds, 1979](#)) and then tested that model with mixed methods on so-called outlier schools that exceeded expectations in neighborhoods with few resources. [Edmonds \(1979\)](#) conceived of instructional leadership as a role carried out by the school principal, a definition that was quickly adopted and utilized for successive studies of effective schools research (e.g. [Bossert et al., 1982](#); [Hallinger and Murphy, 1985](#); [Leithwood and Montgomery, 1982](#)).

According to Murphy's findings, effective instructional leaders (a) develop mission and goals; (b) promote quality instruction through supervision; (c) promote a positive learning culture through rewards, high expectations, and professional development; and (d) develop a safe and orderly school environment with appropriate economic and community resources. Murphy drew upon organizational perspectives to consider organizational processes and structures that support classroom instruction. Similarly, [Hallinger \(1984\)](#) identified several "instructional leadership behaviors" that yielded improved student outcomes—namely, setting high expectations and goals, supervising, and evaluating instruction, coordinating the curriculum, and monitoring

student progress. Hallinger and Murphy (1984) did not, however, find any connections between curriculum decision-making structures or learning culture and student achievement. Essentially, early instructional leadership models emerged from an empirical base that quantitatively measured principals' tasks and functions as variables that contributed to student outcomes in effective low-SES schools.

In this literature of the 1980s, it is important to note that relatively little reference was made to teachers, department heads or assistant principals as instructional leaders; there was little emphasis on instructional leadership as a distributed construct or a function to be shared. Instructional leaders were described as strong, directive leaders who had been successful in "turning their schools around" (Edmonds, 1979; Hallinger and Murphy, 1985); relatively few case examples of instructional leaders were conducted in schools with average or high performance in the early studies of the 1970s and 1980s. Drawing on results across this literature as well as their own empirical findings using survey methods, Hallinger and Murphy (1985) identified three dimensions of instructional leadership: (1) defining the school's mission, (2) managing the instructional program, and (3) promoting a positive school learning climate delineated into ten instructional leadership functions in educational organizations, including framing the school goals, supervising and evaluating instruction, coordinating curriculum, monitoring student progress, protecting instructional time, providing professional development, maintaining high visibility, providing incentives for teachers, and providing incentives for learning. Hallinger utilized his research over time to develop a rating scale for instructional leadership.

Shephard (2014) replicated Hallinger's study and identified the additional school factors of teacher commitment, professional involvement, and innovativeness as essential influences on classroom practice (with *practice* defined as instructional processes and student behavior). Similarly, other studies assumed a focus on the principal's leadership practices, including most often supervision and staff development, that contributed to improvements in teacher instruction (e.g. Blasé and Blasé, 1999; Heck et al., 1990; Leithwood and Duke, 1998). These studies also included a focus on motivation variables defined in psychology and learning theories rather than curriculum theory or education theory that might have illuminated the leader's work through sociopolitical and historical lenses essential for understanding diverse experiences (Pinar, 2004). At the same time, while early instructional leadership literature focused on structures and processes that support learning in classrooms, they did not explicitly account for change in ways that transformational leadership theories articulated.

Transformational leadership

In probably the most frequently cited example of transformational leadership, Leithwood (1994) posited a framework for transformational leadership elements that explicitly acknowledged change in educational organizations. He later conducted a meta-analysis (Leithwood and Riehl, 2003) of additional effective leadership studies and a North American research project (Leithwood and Seashore, 2011), indicating that four leadership practices were necessary but not sufficient for effectiveness in any context: setting directions, developing people, redesigning the organization, and managing the instructional program. Leithwood and Seashore (2011) concluded, based upon a mixed methods study with a large North American sample, the effects of leadership influence on student outcomes is indirect. Teaching or instruction and related classroom practices have a direct causal effect. Robinson (2010) conducted a synthesis of literature on instructional leadership and concluded that "while there is considerable evidence about the impact of instructional leadership on student outcomes, there is far less known about the leadership capabilities that are required to confidently engage in the practices involved" (p. 1–2). Her research suggested the importance of three interrelated capabilities: (a) using deep leadership content knowledge to (b) solve complex school-based problems, while (c) building relational trust with staff, parents, and students. Robinson (2010) argued that there is considerable interdependence between these three capabilities. Moreover, in an earlier synthesis of research, Robinson et al. (2008) concluded that the effect of instructional leadership on student outcomes was three to four times as great as that of transformational leadership. Here instructional leadership refers to those sets of leadership practices that involve the planning, evaluation, coordination, and improvement of teaching and learning. Going further with an emphasis on indirect relationships among leadership, instruction, and learning outcomes, Murphy et al. (2006) referred to instructional leadership with these capabilities as learning-centered leadership. Robinson et al.'s secondary analysis identified the relative effects of five sets of leadership dimensions: leading through promoting and participating in teacher learning and development; establishing goals and expectations; planning, coordinating, and evaluating teaching and the curriculum; strategic resourcing and ensuring an orderly and supportive environment. Robinson and colleagues concluded from these two meta-analyses that the more leaders focus their relationships, their work, and their learning on the core business of teaching and learning, the greater their influence on student outcomes (Robinson et al., 2008).

Shared or distributed leadership

Other recent studies have continued a focus on "instructional" leadership beyond the exclusive domain of the principal since teachers and other support professionals play a vital leadership role in the improvement of classroom practices (e.g. Hallinger, 2004; Jackson, 2000; Marks and Printy, 2003). Such a shared or integrated model conceptualizes instructional leadership as a capacity for school improvement in which the principal models appropriate instructional leadership behaviors (Bossert et al., 1982; Hallinger and Murphy, 1984; Purkey and Smith, 1983; Shephard, 2014) and invites teachers and others to join their efforts to change and improve their teaching practices. For example, Jackson (2000) used a mixed-methods approach to examine schools that consistently performed well on various assessment measures; he found that an "interactive leadership model"—whereby principals invited teachers to lead instructional improvement efforts and then worked with them in a shared instructional leadership

capacity to develop instructional innovations—could improve student learning. Like earlier instructional leadership studies that focused on individual principals, Jackson emphasized the distributed leader's role in pedagogical improvements more than curriculum content decisions. Spillane et al. (2001) come closer to an interdisciplinary perspective when they define distributed instructional leadership in terms of the various forms of capital that followers value (e.g. social, cultural, human). Here Spillane et al.'s definition of *human capital* encompasses academic content knowledge and implies the importance of leaders' understandings about students and their backgrounds. In other words, traditional (principal-focused) and distributed instructional leadership models account for instructional leaders' abilities to recognize excellent instruction but not necessarily leaders' abilities to foster rigorous instruction that recognizes diverse students' assets or funds of knowledge or to engage teachers and others in complicated conversations about equitable access to excellent curriculum content and instruction for *all* students. Other scholars (e.g. Kelley and Halverson, 2012; Klar, 2012; Moos et al., 2004; Møller, 2006) have considered instructional leadership as a distributed construct, drawing on Spillane's (2012) research to consider how social networks affect such objects as curriculum and instruction. According to Harris (2007), this view of distributed instructional leadership also rests on an idea of leadership as cognition as well as an idea of leadership as mediating social networks and the capital needed to develop democratic features. At the same time, these distributed leadership approaches to leadership for learning do not always explicitly address social justice. A social justice orientation toward instructional leadership is considered below.

Instructional leadership for academic, social justice, and equity

More recently, a growing number of scholars have expanded instructional leadership to focus on social justice with regard to curriculum and instruction (e.g. Oakes et al., 2000; Scheurich, 1998; Theoharis, 2007; Touchton and Acker-Hocevar, 2001). For instance, Touchton and Acker-Hocevar (2001) examined schools that were restructured to improve academic performance for students from traditionally marginalized groups. In this study, the school was the unit of analysis; however, Touchton and Acker-Hocevar focused on the role of the leader in the development of inclusive decision-making processes and classroom instructional practices. Likewise, Dantley and Tillman (2006) examined school restructuring and policy change efforts aimed at transforming procedures that perpetuate social inequalities and marginalization attributable to race, class, gender, and other markers of otherness.

Focusing more specifically on the leader, Theoharis (2007) studied principals' social justice orientations and argued that leaders must create inclusive instructional programs that account for race, class, gender, disability, sexual orientation, and other historically and currently marginalizing conditions (p. 223). Furthermore, Theoharis argued that to challenge the status quo of currently marginalizing instructional practices, such as segregating special education students, social justice leaders must have ideological clarity, self-awareness, passion, and courage. Frattura and Capper (2007) agree, arguing that the primary leadership characteristic of social justice leaders is that "leaders must believe in their core that students learn best when they are educated in heterogeneous educational settings" (p. 19). These and other social justice leadership studies move the needs of traditionally marginalized groups to the center of instructional leaders' efforts and push instructional leadership to incorporate dispositions and practices associated with critical theory (e.g. ideological clarity, critical self-awareness, aims for radical social change).

Marshall (2004, p. 7) argues that for leaders to develop critical self-awareness and ideological clarity, educational leadership preparation programs must have "more skills beyond scientific management or quick fixes" (p. 43) to address complex educational dilemmas steeped in an array of social, cultural, and political contexts. More specifically, McKenzie et al. (2008) posit three goals for educational leaders who seek educational equity and excellence: (a) They must believe that high test scores matter and raise the academic achievement for *all* students in the school, (b) they must prepare their students to live as critical citizens in society, and (c) they must recognize that both of these goals can be achieved only when leaders assign students to inclusive, heterogeneous classrooms that provide all students with access to a rich and engaging curriculum. According to McKenzie and colleagues, a critical consciousness about power, privilege, and social inequities motivates leaders to ensure that schools are safe places for all children and that academic achievement is explicitly linked with activism. To date, the literature on social justice and social equity leadership has primarily documented how principals have raised the achievement of typically marginalized students and, in some cases, done so in inclusive ways (e.g. Capper and Young, 2014; Dantley and Tillman, 2006; Theoharis, 2007; Touchton and Acker-Hocevar, 2001; Moral et al., 2020). As a result, instructional leadership preparation has expanded to include a clear focus on social justice and equity as well as instruction and learning.

Essentially, across this literature, leaders who create equity, which is different from equality, move beyond making sure that all children are treated the same, to ensuring that all students are succeeding academically the same (Larson and Murtdha, 2002). In other words, according to empirical research inspired by critical education theorizing, school leaders with this orientation are activist leaders who work to create justice in schools for all students (Bogotch, 2000; Capper, 2014; Capper et al., 2013; Dantley and Tillman, 2006; Jean-Marie, 2008; Marshall and Oliva, 2012; Shields, 2004). In contrast to earlier instructional leadership focused on planning, evaluation, coordination, and improvement of teaching and learning for individual student achievement and school improvement, this literature strand focuses on equity and social justice through curriculum and instruction. Such aims of social change require leaders to focus attention beyond schools and classrooms to community in ways that support students with culturally diverse backgrounds.

A number of scholars have recently developed culturally responsive leadership approaches to support social change aims (e.g. Horsford et al., 2011; Johnson, 2006, 2014; Scanlan and López, 2014). Johnson (2006) was one of the first to extend the asset-based approach of culturally responsive pedagogy to leadership. Johnson (2006) defined culturally responsive leadership as leadership

that involves philosophies, practices, and policies that create inclusive schooling environments for students and families from ethnically and culturally diverse backgrounds. Common practices include (1) emphasizing high expectations for student achievement; (2) incorporating the history, values, and cultural knowledge of students' home communities in the school curriculum; (3) working to develop a critical consciousness among both students and faculty to challenge inequities in the larger society; and (4) creating organizational structures at the school and district level that empower students and parents from diverse racial and ethnic communities (Johnson, 2007). Other researchers (e.g. Scheurich, 1998; Johnson, 2006, 2007). Riehl (2009) identified similar characteristics and practices of culturally responsive leadership.

Further, Horsford et al. (2011) incorporated antiracist pedagogy and leadership in diverse contexts to create a framework for culturally relevant leadership, including four dimensions: (1) knowledge of the political context; (2) inclusion of a culturally relevant and antiracist pedagogical approach; (3) a personal knowledge of cultural proficiency and challenges to it; and (4) the professional duty to work for educational equity. As Johnson (2014) and others have noted, culturally responsive leadership often overlaps with leadership for social justice approaches, a term that has been prevalent in the US educational leadership literature and focuses on improving the educational experiences and outcomes for all students, particularly those who have been traditionally marginalized in schools. Most recently, Johnson (2014) applied culturally responsive leadership to practices that bridge school and community concerns, advocate for cultural recognition and revitalization, and position educational leaders as advocates for racial equity and community development in diverse neighborhoods (p. 7).

Scanlan and López (2014) agree with the need to bridge school and community concerns and add explicit attention to cultural and linguistic diversity. Scanlan and López draw on culturally responsive leadership practices that reduce marginalization and successfully educate what they term the new mainstream of students. Based upon their analysis of the literature, Scanlan and López identified three essential dimensions to effectively educate culturally and linguistically diverse students, including promoting socio-cultural integration, cultivating language proficiency, and ensuring academic achievement. They proposed a theory of action that school leadership most effectively creates the learning architecture for successfully educating culturally and linguistically diverse students through an integrated service delivery.

In a recent review of literature on equity-oriented leadership, Leithwood (2021) identified practices and dispositions of equity-oriented leaders that contribute to inclusive, socially just educational experiences for diverse students in their schools. Drawing on his synthesis of literature on social justice, equity, and leadership, Leithwood (2021) identified common practices and dispositions of equity-oriented leaders. Findings indicated that successful equity-oriented leaders stress the importance of authentic school, family and community partnerships, recruit and retain a teaching staff reflecting the diversity of the school's students and families and develop a proactive disposition within the school. Within the classroom, leaders help teachers advance equity when they encourage and support ambitious forms of instruction and implement a curriculum perceived by students to be meaningful (e.g. culturally responsive). Importantly, Leithwood (2001) noted that the conception of leadership identified across the literature is a distributed one.

While culturally responsive and social justice-oriented leadership has contributed to the knowledge base about leadership for learning as well as social equity, like the instructional leadership studies, these studies do not explicitly consider education theory concepts (Dewey, 1887, 1916) like growth, pedagogical relations, experience, and the environment. Further, in the first strand, there is a preponderance of quantitative or mixed methods, and in the second strand aimed at equity, there is a preponderance of qualitative studies (Briggs et al., 2012).

Education theorizing and concepts

In the late 1800s and early 1900s, during another time of demographic changes due to immigration changes and industrialization, John Dewey formulated his education theorizing, considering both individual and social growth as well as the tensions between these. Dewey's education theorizing drew heavily on a continental tradition with its emphasis on a dialectic or tensions between competing forces but an ultimate aim of education for humanity (1877, 1938). For Dewey, education required a humanistic approach that supported both individual development and social aims. In *My Pedagogic Creed*, Dewey (1897/1972) told us:

I believe that education is a regulation of the process of coming to share in the social consciousness; and that the adjustment of individual activity on the basis of this social consciousness is the only sure method of social reconstruction I believe that in the ideal school we have the reconciliation of the individualistic and the institutional ideals (p. 93).

Here Dewey's (1897/1972) education theorizing aimed at unifying the individual journey and the societal goal of education: "education must be conceived as a continuing reconstruction of experience ... the process and the goal of education are one and the same thing" (p. 91). As he argued in *My Pedagogic Creed*,

I believe that the only true education comes through the stimulation of the child's powers by the demands of the social situations in which he finds himself. Through these demands he is stimulated to act as a member of a unity, to emerge from his original narrowness of action and feeling and to conceive of himself from the standpoint of the welfare of the group to which he belongs. Through the responses which others make to his own activities

he comes to know what these mean in social terms. The value which they have is reflected back into them. For instance, through the response which is made to the child's instinctive babbling the child comes to know what those babblings mean; they are transformed into articulate language and thus the child is introduced into the consolidated wealth of ideas and emotions which are now summed up in language.

Dewey (1916, p. 493) summarized his views about the child and the curriculum in *Democracy and Education*:

In sum, I believe that the individual who is to be educated is a social individual and that society is an organic union of individuals. If we eliminate the social factor from the child we are left only with an abstraction; if we eliminate the individual factor from society, we are left only with an inert and lifeless mass.

Dewey went on to argue, "We never educate directly, but indirectly by means of the environment." The influence of the environment operates through the habits of language, manners, good taste, and esthetic appreciation. These define the demands of social situations or the environment that contextualizes children's experiences in the world (Henderson et al., 2021). As Dewey put it, "In order to know what a power really is, we must know what its end, use, or function is; and this we cannot know save as we conceive of the individual as active in social relationships. But, on the other hand, the only possible adjustment which we can give to the child under existing conditions, is that which arises through putting him in complete possession of all his powers" (Dewey, 1897, p. 6). For Dewey, the individual followed his/her own journey of growth yet also connected and developed in social relationships as part of a democratic way of living.

Importantly, Dewey also reminded us that education must recognize that the future is an open question. He continued later in *Democracy and Education* (Dewey (1916).

With the advent of democracy and modern industrial conditions, it is impossible to foretell definitely just what civilization will be twenty years from now. Hence it is impossible to prepare the child for any precise set of conditions. To prepare him for the future life means to give him command of himself; it means so to train him that he will have the full and ready use of all his capacities; that his eye and ear and hand may be tools ready to command, that his judgment may be capable of grasping the conditions under which it has to work, and the executive forces be trained to act economically and efficiently.

In other words, Dewey (1897, 1916, 1938) encouraged continuous growth throughout life, and to avoid following a path to a point where learning could stop. In *Democracy and Education*, Dewey (1916) argued, in particular, that an education which only emphasizes the achievement of "external aims" (e.g. evidence from standardized test scores, grades, school letter grades, etc.) hinders students' capacity for continuous growth and leads students toward viewing learning as an overly burdensome activity which they should seek to end as quickly as possible. Rather, in a Deweyan notion of democratic society, there is a reliance on ordinary individuals increasing their wisdom through experience. Reality for Dewey is constantly changing and there is no one with a monopoly on the knowledge of reality which means that democracy requires that everyone continuously grow and adapt to changing conditions.

It should be noted that Dewey (1916) did not ignore the significance, nature and utility of subject areas, or outcomes. In fact, chapters of *Democracy and Education* are dedicated to deliberation on "geography and history" and "physical and social studies" as well as "play and work" and "vocational aspects of education." Dewey communicates the aims of education for social direction, preparation, formation, and reconstruction. Consequently, education is "based upon a consideration of what is already going on; upon the resources and difficulties of existing conditions," all of which require reflection and development or growth (democracy) (p. 493).

In Dewey's (e.g. 1897, 1916, 1938) writings, we gain a philosophical approach to education that requires individual growth, reflection, and social development (democracy). We see a way to hold the individual's needs at tension with needs for a common societal aim toward democracy. Dewey's education theorizing was developed during an earlier time when the US was developing as a nation state out of immigration amid wars and a pandemic. Here individual growth includes academic learning as part of an individual journey of understanding in relation to needs of society. During his career, Dewey opened a lab school aimed at the individual and society, but he did not explicitly consider the role of the organization or leadership support for instruction and pedagogy in ways that leadership scholars have emphasized. Dewey's work was pragmatic in nature; however, he did not conduct empirical studies drawing on his education theorizing.

Implications and conclusions: theorizing leadership for education and learning

Drawing on the extant empirical leadership literature aimed at effective instruction, learning, and schools, and Dewey's education theorizing aimed at the individual in relation to society, the purpose of this chapter was to consider leadership for

learning in relation to changing demographic, education, and policy contexts. By 2015, the US is projected to become a majority minority nation state due to immigration and internal demographic shifts. Such increasing cultural diversity is, in some ways, at tension with policy trends toward evidence-based programs, more centralized curriculum, and externalized evaluations. Today's leaders must mediate and balance these tensions in order to support education and learning for individuals and a democratic society.

Across the extant leadership literature, we can find two dominant strands with some distinctive aims. First, literature on instructional leadership focused on the principal and his/her support for instructional improvements aimed at student learning outcomes. Here, leadership support tends to be organizational, structural, or programmatic with learning outcomes from these measured with empirical research and externalized evaluations. This pattern makes sense because much of the literature on "instructional" leadership or leadership for learning is frequently grounded in organizational theory and policy trends support evidence-based programs. We can observe similar trends in other dominant leadership approaches (e.g. transformational leadership) with the additional focus on change.

In the other literature strand reviewed here, the aim is much more clearly grounded in critical theories with a focus on societal change and equity, and this literature strand provides important understandings about leadership for learning and equity. In John Dewey's (e.g., 1897, 1916, 1938) education theorizing, we can see an example of how to balance tensions between diversity and commonality in a dialectic approach; we recall from Dewey about longstanding conceptual understandings of education, growth and pedagogy that link the development of individuals and society. At the same times, Dewey's pedagogy does not include explicit attention to culturally responsive pedagogy or leadership.

Future *educational* leadership research and preparation grounded in education theorizing with understandings about tensions in a dialectic and implications for pedagogy as well as leadership grounded in organizational theory and change may offer a new framework for study and practice (Uljen and Ylimaki, 2017; Ylimaki and Uljen, 2017). In my view, implications for leadership preparation involve a greater emphasis on curriculum, philosophy, and foundations of education, including background in culture, as well as empirical evidence (Ylimaki, 2012; Ylimaki and Uljen, 2017). To date, much of the educational leadership literature is empirical in nature. Knowledge from empirical study has made significant contributions, but empirical study alone may not be insufficient to guide educational leaders in an increasingly complex policy and demographic context. Today's leaders who serve increasingly culturally diverse students at tension with policy requirements for common curriculum standards and externalized evaluations amid other complexities would also benefit from study of dialectics and education concepts from Dewey and the roots of his work as well as theories of organizations and culture, recognizing the future as an open question (Kraus and Ylimaki, *in press*).

Introduction

What is theory? What is theory for? What are the theories that make up the current theoretical groundings in educational leadership research? How to contribute to theory development in educational leadership? This chapter aims to answer these questions. To peek into the future of theoretical groundings of educational leadership, we need a grip on the past and present. With an eye toward the future, I first chart advances over the past decades about what theories have been frequently used to frame empirical studies in educational leadership research. After taking stock of many past studies, I provide readers with two recommendations for theory development in educational leadership.

What is theory?

What is theory? This has been a long-standing question in the field of educational leadership. Asking educational leadership researchers, you may receive different answers. Some researchers use many terms interchangeably, including “theory,” “concept,” “construct,” “theoretical,” “conceptual,” “theorize,” and “conceptualize.” Others believe that nuances exist to differentiate those terms. In a recent article on the absence of student-centered learning in educational leadership, the authors stated, “all functions of leadership must stem conceptually, theoretically and practically from our understanding of the principles of learning” (Myran and Sutherland, 2019, p. 661). It seems the authors attached different meanings to “conceptually” and “theoretically.” Yet it is unclear what differentiated the two terms. The definition of theory has been quite confusing for many educational leadership researchers and practitioners.

What “theory” means can vary from one paper to the next (Abend, 2008). To set the stage for a discussion on the future theoretical groundings in this chapter, I introduce two major definitions of theory in educational leadership research. First, a theory can be logical propositions that establish testable hypotheses about the relationships among constructs (Leavitt et al., 2010). In this vein, a theory has two elements: (1) the constructs, “to which a particular meaning has been attached” (Griffiths, 1983, p. 38), as the building blocks of a theory, and (2) the assumptions of construct relationships (Wang, 2018a, b). To understand something, we have to start somewhere by labeling it. Social capital is a construct, meaning the sum of resources an individual or a group can access. A theory of social capital needs to propose some relationships among constructs. Take Burt’s (2005) social capital of structural holes as an example. This proposition established the relationship between social capital and structural holes. To build social capital, according to Burt, it is insufficient to simply build social ties. Rather, it is uniquely advantageous to build a specific type of ties—the ties that function as a bridge connecting holes in network structures. In Fig. 1, both Abby and Bill have four social ties, but they do not have the same amount of social capital. There is no structural hole in Abby’s social network, because everyone in Abby’s social network is connected to one another. By contrast, each tie connected to Bill functions as a bridge to a different pool of resources. The ties between Bill and Individual 2, 5, 6, and 8 enable Bill to access to resources in Group A, B, C, and D, respectively. Using the social capital of structural holes, researchers can conduct empirical research to expand existing theory—such as by adding mediators or moderators—or present new theories (Leavitt et al., 2010). In this sense, much of the research in educational leadership is “better labeled theoretically oriented than theory” (Willower, 1975, p. 4). This definition of theory is quite stringent.

Fig. 1 Do Abby and Bill have the same amount of social capital?

A theory can also be an explanation of a particular social phenomenon. When we say that we have a theory about leadership, what we mean is that we can offer an explanation of it. This explanation should identify a number of factors or conditions (Abend, 2008). Many theories about leadership styles fall into this category. Leadership can be explained by leader behaviors. A pattern of leader behaviors is then considered as a leadership style (Wang, 2019). For example, transformational leadership presents an explanation of leadership, and this explanation has four dimensions: idealized influence, inspirational motivation, intellectual stimulation, and individualized consideration (Bass, 1998). Ethical leadership can be explained by leader behaviors in seven dimensions: fairness, integrity, ethical guidance, people orientation, power sharing, role clarification, and concern for sustainability (Kalshoven et al., 2011). Culturally responsive school leadership presents another explanation of leadership, which encompasses four dimensions: critically self-reflecting on leadership behavior, developing culturally responsive teachers, promoting culturally inclusive school environment, and engaging students, parents, and indigenous contexts (Khalifa et al., 2016). Another example is organizational justice, which is closely related to organizational outcomes (e.g., employee job satisfaction, organizational commitment, organizational citizenship behavior, and organizational performance). Organizational justice has four dimensions: distributive, procedural, interpersonal, and informational justice (Colquitt et al., 2001). Building on these theories, researchers can use empirical research to evaluate and integrate the theories into other theories, thereby developing new theories. For example, shared instructional leadership was proposed after integrating instructional leadership and transformational leadership (Marks and Printy, 2003). Latino Critical Theory (LatCrit) was proposed after applying critical race theory and adding dimensions of language, immigration, ethnicity, culture, identity, phenotype, and sexuality to explain Latinas/Latinos' multidimensional identities and address the intersectionality of racism, sexism, classism, and other forms of oppression (Alemán, 2009; Bernal, 2002).

The above two definitions of theory are consistent with the saying, "empirical research should make a *theoretical* contribution." Granted, theory can also mean "an overall perspective from which one sees and interprets the world" (Abend, 2008, p. 179), such as postmodern theory, poststructuralist theory, feminist theory, queer theory, and critical theory. They are more about philosophical viewpoints on how to see and interpret the world, but less about the specific constructs and the relationships among them (Willower, 1980). A theory explains the essential elements of *what* (e.g., constructs and variables), *how* (e.g., How are the constructs and variables related?), and *why* (e.g., the underlying assumptions that justify the selection of the constructs and variables and the proposed relationships). A good theory is not a list of variables or the addition of a new variable to an existing list. Empirical evidence, according to (Poincare, 1902), is analogous to stones used to build a house. A pile of stones is not a house, and a pile of constructs and variables does not constitute a theory. By contrast, a good theory constitutes description and explanation—"a plausible, cogent explanation for why we should expect certain relationships in our data" (Whetten, 1989, p. 491). Kuhn's (2012) description of theory was even more detailed, "theories should be accurate in their predictions, consistent, broad in scope, present phenomena in an orderly and coherent way, and be fruitful in suggesting new phenomena or relationships between phenomena" (p. xxxi). Given that many educational leadership studies were only theoretically oriented (Willower, 1975), the term "theory" in this article is inclusive, encompassing both definitions introduced above, including a set of constructs, assumptions, and generalizations serving to explain a phenomenon.

What is theory for?

What is theory for? In other words, what are the functions of theory? With ever-increasing data—along with sophisticated measurements and data analyses, why not letting data speak for themselves—without a theoretical framework? To answer these questions, it is important to first look into three strands of a discipline or field: theoretical, methodological, and evaluative strands (Kuhn, 2012). Each strand represents an essential dimension of the disciplinary matrix: theories guide research by bringing clarity in explaining

phenomena; research methods allow empirical work to produce results that eliminate the ambiguities of theories; evaluative standards serve as a means “to scrutinize theories in great empirical detail” (Kuhn, 2012, p. 42). Taken together, the three strands are entangled, interwoven in research to advance a field. The development in one strand influence other stands, and vice versa.

A primary function of theory is to allow generalization, which derives from empirical evidence, to explain a phenomenon. The phenomena of interest are “too complex and varied to be explored at random” (Kuhn, 2012, p. 109). To study the phenomena of interest, it is too mentally demanding, if not cognitively impossible, to probe in all directions. Without theory, how can we decide what should be observed? It is theory that guides researchers as they explore the entities involved in the phenomena and how the entities behave. If you are a researcher or aspire to be one, the key is to ask good research questions. Theories help you do that. How? Here is an example. In crime TV shows, detectives examine existing evidence, generate their theory to explain what happened at a crime scene, and then find further evidence to either support or refute their theories, and maybe come up with new theories to explain new evidence. In their cases, the detectives’ theories are constantly evolving with the newly uncovered evidence. This process is very similar to the functions of scientific theories, as detectives always say, “Follow the evidence!” Theory in scientific research functions as an engine to generate concrete explanations of phenomena. Researchers use theories to derive assumptions and constructs in intellectual inquiry. Without theory, research methods are devoid of reasoning. For example, listing variables and their relationships without explanatory text is not theory-driven research. Theory forces researchers to dig into theoretical explanations and use logical reasoning.

In a field as interdisciplinary as educational leadership, theory is essential to empirical research (Van Maanen et al., 2007). This is why every empirical article in the field is required to include a section of theoretical framework. In the 1950s when educational leadership was still at its inception, Griffiths (1959) described a theory of administration as (1) a guide to action, (2) a guide to the collection of facts, (3) a guide to new knowledge, and (4) a guide to explain the nature of administration. After decades of development, educational leadership research addresses an ever-broader set of issues in an ever-increasing diversity of settings and more deeply embedded in its interdisciplinary knowledge base, including psychology, sociology, sociopsychology, and economics (Wang and Bowers, 2016). Given the interdisciplinary nature of educational leadership, theory is more important than ever.

Where have we been?

Before peeking into the future, it seems sensible to look back and take stock of theories that have been used to frame empirical research in educational leadership. Theories about educational leadership abound. In the 1950s, the theory movement was launched to respond to the mounting dissatisfaction with the “poverty of theory within our own field” and the criticism that “our own research has been anchored in naked empiricism” (Halpin, 1970, p. 156). Heavily influenced by logical positivism, the theory movement favored a cumulative, generalizable knowledge base built from rigorous, hypothetical-deductive empirical research and aimed at building a unique theory for educational leadership (Culbertson, 1988; Getzels, 1977; Griffiths, 1983; Halpin, 1970). Walton’s (1955) lamented that educational leadership lacked “a well-defined, highly organized body of subject matter; it has no elegant simple theoretical structure; and as literature it is singularly devoid of esthetic qualities” (p. 169). To build a unique theory for educational leadership, researchers ventured into the theories in other fields.

From the outset in the 1950s and the 1960s, theories in educational leadership were rooted in the theories in the social and behavioral sciences (Bates, 1980; Boyan, 1981; Hoy, 1982; Oplatka, 2009; Walton, 1955; Willower, 1975). This laid the foundation for educational leadership as an interdisciplinary field. The theoretical groundings of educational leadership have grown rapidly since the 1950s, particularly over the last two decades of the 2000s and 2010s. Fig. 2 illustrates the growth of the theoretical groundings of educational leadership since 1999. In each network, a node represents a theory that was used to theoretically frame empirical studies published in four leading educational leadership research journals: *Educational Administration Quarterly*, *Journal of Educational Administration*, *Educational Management Administration & Leadership*, and *Journal of School Leadership*. A tie connects a pair of theories if they were used to frame the same article. As seen in Fig. 2, the theory co-occurrence networks have grown rapidly in terms of both network size and complexity. By the end of 2018, a total of 483 theories were used to frame empirical articles theoretically. If we zoom in onto the center of the network in 2018, we can see the theories at the center of the network were the ones that were frequently used to frame empirical articles (See Fig. 3). Those theories fall into four categories: (1) theories about leadership styles (i.e., theories explain patterns of leader behaviors), (2) theories in organizational context (i.e., theories explain collective behaviors and phenomena in organizations), (3) sociological, psychological, and socio-psychological theories (i.e., theories explain mental processes which are manifested through behaviors), and (4) theories about social justice (i.e., theories explain justice, equity, diversity, and inclusion in schools as organizations). This categorization is not mutually exclusive, as they are all closely interconnected to one another in Fig. 3.

Theories about leadership styles

Many educational leadership studies took a behavioral approach, focusing on leader behaviors. When leader behaviors show a pattern, such a pattern is considered as a leadership style. Given the two definitions of theory in the earlier section, the theories about leadership styles do not fit the first definition which is very stringent, but fit the second definition which is offering explanations of a particular social phenomenon of leadership. Notably, other terms—such as leadership models and leadership approaches—bear similar, if not the same, meaning as leadership styles. Nevertheless, the leadership styles that have been frequently used to frame

Fig. 2 Theory co-occurrence network of educational leadership from 1999 to 2018

Fig. 3 Theories at the center of the theory co-occurrence network of educational leadership

Note. Node size indicates weighted degree centrality. The bigger the node size is, the more central a theory is in the network. Node color differentiates clusters detected by calculating the modularity score for each node.

empirical research include distributed leadership, instructional leadership, transformational leadership, social justice leadership, and teacher leadership (Wang, 2018a, b).

The theoretical roots of many leadership styles can be traced back to the literature in neighboring fields, including social behavioral science, psychology, organizational science, and administrative science (Boyan, 1981; Haller, 1968; Walton, 1955; Willower, 1975). For example, distributed leadership has its theoretical root in distributed cognition and activity theory (Spillane et al., 2001). Transformational leadership emerged in the body of literature that had a broad interest in leadership—not necessarily in schools but rather in all sorts of organizations and social groups (Bass, 1985), and then was applied to school settings (Leithwood, 1994).

After decades of theory development, some of the dominant leadership theories (e.g., distributed leadership and transformational leadership) remain as the mainstream in the field of educational leadership. Moreover, educational leadership scholars have developed theoretical explanations that are unique to educational organizations with a focus on teaching and learning, such as instructional leadership, teacher leadership, and leadership for learning. This appreciable progress spotlights the teachers and their instructional activities that are unique in school contexts in comparison with the leadership in non-school context (Greenfield, 1995).

Further, a wide range of theories has been used to explain educational leadership. In addition to the aforementioned theories, other theories include ethical leadership, democratic leadership, and participative leadership (Oplatka, 2010). Arguably, the latter two theories were very similar to distributed leadership which turned the focus from leaders at an individual level to a broader context. Instead of viewing leadership as extraordinary individuals with distinctive qualities and virtues, distributed leadership posited that leadership was the outcome of the interaction of leaders, followers, and situation (Spillane, 2006). The situation was mostly contextualized in schools as organizations (Bolden, 2011). Since 2000, in addition to distributed leadership, social justice leadership has gained traction in educational leadership, as evidenced by the rise of social justice-themed theories, such as social justice theory, critical race theory, and culturally responsive school leadership (Wang, 2018a, b)—a point I will return to shortly.

Theories in organizational context

In addition to leadership styles, another group of frequently used theories in educational leadership research is closely related to organizational context. The theories include organizational theory, organizational learning, organizational culture, and institutional theory. These theories were mostly borrowed from the neighboring field of organizational science (Oplatka, 2014).

In the 1950s and 1960s, social system and role theory were considered as major theories in educational leadership. These theories conceptualized a school and its people were in a closed-system organization, in which the absence of social, economic, and political impact was palpable (Hoy, 1982). In the 1970s, researchers acknowledged a “contingency-laden human context” of education leadership (Culbertson, 1981, p. 41). Instead of theorizing schools as a closed system marked with scientific management, bureaucracy, and social process theory, schools were considered as an open system. Universal theories of organizations were replaced by contingency theory (Hoy, 1982). Contingency theory considered the external environment (e.g., cultural, political, economic, informational and technical, and physical factors) as a moderator that influences the relationships between leadership and internal adjustments in organizations (e.g., decision-making process, structure, policies, practices, and organizational performance; Hanson, 1979). Despite theoretical advances, contingency theory was too inclusive because it suggests “it all depends.” Willower (1980) even questioned “whether contingency theory is a theory in the first place. Put another way, is contingency theory a set of related concepts and generalizations that serve to explain or is it a broad injunction to focus on the complexity of relationships and the contingency that affect them?” (p. 4).

In the 1980s the 1990s, as a response to the seminal report *A Nation at Risk: The Imperative for Educational Reform* (The National Commission on Excellence in Education, 1983), the rising interest in educational reform and school effectiveness (Oplatka, 2010; Wang et al., 2017) gave rise to a set of theories that address organizational change and reform. To study how to facilitate organizational change and reform in schools, many studies drew on organizational theories that were used in organizational science, including loosely coupled theory, organizational culture, organizational climate, bureaucracy, and empowerment.

From the 2000s to 2010s, there was an increasing number of theories that explained human behaviors in organizations and organizational outcomes. Among them, institutional theory, proposed by DiMaggio and Powell in the 1980s, was frequently used to frame research about organizational change. Institutional theory explained why organizations were so similar, regardless of who the leaders were. According to institutional theory, leaders have little impact, because organizations are exceedingly resistant to change, swept along by external forces, and constrained by norms (DiMaggio and Powell, 1983). However, there was a competing view derived from strategic leadership, which considered that leaders’ characteristics (e.g., personality, cognition, charisma, power, knowledge, skills, and abilities) greatly influence what happens to their organizations (Samimi et al., 2020). In educational leadership research, scholars investigated the relationship between school leadership and student achievement (Hitt and Tucker, 2016; ten Bruggencate et al., 2012; Witziers et al., 2003). In addition to student achievement as an organizational outcome, other theories about organizational outcomes were also frequently used in educational leadership research. Those theories included organizational citizenship behavior, organizational commitment, and employee job satisfaction. Moreover, as a response to the earlier criticism of contingency theory, researchers have worked to mitigate ambiguity and uncover intricacies in different contexts, including accountability policy implementation, teacher performance improvement in urban schools, and building organizational culture in turnaround schools. With student demographics changes, increasing attention has been devoted to how community values were manifest in school board elections, policymaking in schools as organizations, and organizational performance (Alsburry, 2003; Sampson, 2019).

Sociological, psychological, and socio-psychological theories

Given that educational leadership is a social process, many theories in sociology, psychology, and socio-psychology offer theoretical lenses for empirical research in educational leadership. These theories included trust, motivation, self-efficacy, collective efficacy, social capital, social exchange theory, and social network theory. These theories were not frequently applied to educational leadership research until the 2000s (Daly, 2010; Howard and Navarro, 2016).

Recently, those neighboring fields of educational leadership have ventured into neuroscience to investigate the brain mechanisms underlying social and psychological processes. In sociology, a subfield of social neuroscience has emerged to investigate human brains as social organs (Lieberman, 2013). In psychology, a subfield of cognitive neuroscience has emerged to investigate brain mechanisms underlying psychological processes (Gazzaniga et al., 2013). In economics, a subfield of neuroeconomics has emerged where behavioral economics, psychology, and neuroscience converge (Glimcher and Fehr, 2014). In organizational science—a field focusing on individual and collective behaviors in organizational context, a subfield of organizational neuroscience has emerged to “understand and incorporate the cognitive machinery behind our thoughts and actions into organizational theory” (Becker et al., 2011, p. 934). In educational leadership, Wang (2019) introduced brain mechanisms about some of the core constructs in leadership, such as trust, vision and envisioning, charisma, social identity, justice, feelings and emotions, and decision making.

Theories about social justice in education

Scholars have been wrestling with education inequities for decades. In 1966, sociologist James Coleman, commissioned by the United States Department of Health, Education, and Welfare, published the *Equality of Educational Opportunity Study*, also known as the Coleman Study (Coleman, 1995). This report uncovered unequal access to educational opportunities by children of different races, color, religions, and national origins. Since then, the Coleman Study has become the most cited report by educational leadership researchers (Wang and Bowers, 2016). However, the theories about education inequity and social justice did not emerge at the center of the theoretical groundings of educational leadership until the 2000s.

Among them, critical race theory and social justice leadership were frequently used to frame educational leadership studies. Critical race theory, first applied in education research in 1995 (Ladson-Billings and Tate, 1995), posits (1) permanence of racism, (2) whiteness as property, (3) counter storytelling and majoritarian narratives, (4) interest convergence, (5) critique of liberalism, and (6) intersectionality (Capper, 2015). Since then, critical race theory has been applied to study education politics (López, 2003), identify leadership practices for social justice and equity (Iverson, 2007), and analyze the language of the Interstate School Leaders Licensure Consortium (ISLLC) and the Educational Leaders Constituent Council (ELCC) standards (Davis et al., 2015).

Closely related to critical race theory is social justice leadership. With a strong emphasis on creating equal opportunities for students from marginalized groups (Furman and Gruenewald, 2004), socially just leaders are action oriented, transformative, committed, persistent, inclusive, democratic, relational, caring, reflective, and oriented toward a socially just pedagogy (Furman, 2012; Theoharis, 2008). They “translate democratic ideals and inclusive notions into concrete practices and redress injustices to meet the needs of diverse groups” (Wang, 2018a, p. 474). Social justice leadership offers an encompassing view on all forms of diversity, including race, class, gender, sexual orientation, disability, among others (Theoharis, 2007). To highlight students with disabilities, inclusion leadership was proposed (DeMatthews and Mawhinney, 2014). To highlight culture, culturally responsive school leadership was proposed (Khalifa et al., 2016). These theories about social justice have been gaining considerable traction over the last two decades, emerging as a core pillar undergirding the theoretical groundings of educational leadership.

What does the future hold?

Where should theory go? The theoretical groundings of educational leadership, as seen in Fig. 2, have grown more diverse than at any time in recent decades. The field has advanced from theories that focused on leadership at an individual level to leadership at the dyadic, group, and organizational levels. However, compared to a relatively large number of theoretically informed empirical studies, research on the theory development in educational leadership has been limited and has attracted scant attention in the research community. To promote theory development, I provide two recommendations for future researchers in educational leadership.

Recommendation 1: refining definitions of theories

The first recommendation is to refine loosely defined and underdeveloped theories. A problem in educational leadership is that many theories are widely used but poorly defined. Some definitions are largely overlapped with existing theories. Take teacher leadership as an example. In more than a decade of literature, teacher leadership was either rarely defined, or was defined ambiguously as mobilizing instructional expertise about teaching and learning to improve instruction and school culture (Wenner and Campbell, 2017). The latter was “closely aligned with both instructional and participative leadership” (York-Barr and Duke, 2004, p. 261). Moreover, in about 20% of teacher leadership studies, distributed leadership was used as the theoretical framework (Wenner and Campbell, 2017). To further complicating matters, when the definitions of two theories become too overlapped and indistinguishable, some scholars begin to use them interchangeably, such as organizational climate and organizational culture.

The definitions of some theories so elusive and overly inclusive that they offer little guidance in empirical research. Take sense-making as an example. Sensemaking, as the name suggests, refers to individuals or groups use prior experiences and knowledge to navigate ambiguous situations, make sense of information, and decide how to respond (Brown et al., 2015; Kiesler and Sproull, 1982). This definition of sensemaking is similar to social cognition which rests on two assumptions: (1) humans have a limited capacity to process all information; and (2) the cognitive process of making sense of information (i.e., perceiving, encoding, storing, retrieving, and inferring) is subject to individual capabilities (e.g., attention), social pressures, and limitations of information search. How school leaders made sense of race was subject to their own racial and role identity, as well as the history of their schools and communities, organizational norms, values, and beliefs (Evans, 2007). Sensemaking is also similar to upper echelons theory, which posits leaders' characteristics (e.g., knowledge, experience, values, personalities, and preferences) function as a filter and a processor of information (Hambrick and Mason, 1984). To do so, they go through a three-step process. Leaders' characteristics influences: (1) field of vision (i.e., the directions leaders look and listen), (2) selective perception (i.e., what leaders actually see and hear), and (3) interpretation (i.e., how leaders attach meaning to what they see and hear). While the content and labels for these constructs differ somewhat from one another, there is also a clear overlap. When it comes to what specific psychological and social processes that leaders' characteristics are converted into the sense they make in an ambiguous situation, it still remains largely a mystery (Hambrick, 2007a, b). Taken together, all these theories (i.e., sensemaking, social cognition, and upper echelons theory) were developed on the premise of bounded rationality—the idea that complex, uncertain situations are not objectively “knowable,” but rather are merely interpretation (March and Simon, 1958).

Neither indistinguishable nor nebulous definition is helpful for theory development in educational leadership. The purpose of defining a theory is to “set boundaries and limits,” and specify “what is included in the construct and what is not” (Yaniv, 2011, p. 590). Definitions are not just semantic clarifications. Rather, they are foundational to understand the scope and magnitude of a phenomenon. Defining and operationalizing a theory establish boundaries for empirical research. Without a clear definition, we lose grip on a phenomenon of interest. In this sense, I recommended that future researchers take up the challenge to refine definitions of theories in educational leadership. But how to do it?

To refine definitions of a theory, it is important to start with evaluating the utility of a theory or construct by applying a fundamental principle of Occam's razor (Banks et al., 2018). Occam's razor is a rule of thumb in science, suggesting that when two explanations of a phenomenon exist, all else equal, the simpler explanation should be employed (Blumer et al., 1987). Put differently, we choose a parsimonious explanation. The principle of parsimony has been recommended to address construct redundancy which was prevalent in leadership research. As a subfield of leadership in the context of education, the principle of parsimony is therefore recommended to evaluate the sheer volume of similar, overlapping, and indistinguishable theories in educational leadership.

To follow the principle of parsimony, the utility of a construct can be evaluated by (1) content validity, (2) convergent validity, and (3) discriminant validity. Content validity means a construct can be used interchangeably with others, and the construct definition is aligned with its measure(s). Convergent validity means different measures of the same construct need to have a degree of consistency. For example, four dimensions of transformational leadership (i.e., idealized influence, inspirational motivation, intellectual stimulation, and individualized consideration) should be somewhat related, but not so highly related as to suggest redundancy. Discriminant validity refers to the distinctiveness of constructs. One approach to evaluate discriminant validity is to compare meta-analytic correlations across the leadership constructs, conduct confirmatory factor analysis, and calculate average variance extracted and composite reliability estimates (Bergh et al., 2016). If the average variance exceeds the squared factor correlation between any two constructs, then a construct is considered to have discriminant validity (Fornell and Larcker, 1981). After reviewing 57 meta-analytic leadership studies, Banks et al. (2018) reported that no evidence was found to indicate moral leadership behavior was distinct from transformational or charismatic leadership behavior.

Despite the wide variety of definitions and conceptualizations of educational leadership, many theories have been loosely defined, conceptually and operationally. To advance the understanding of educational leadership, it is therefore recommended that future researchers follow the principle of parsimony, evaluate theories by the content, convergent, and discriminant validity, better define and bring clarity to constructs and variables, and set theoretical boundaries in empirical research.

Recommendation 2: pruning theories

My second recommendation is to use empirical research to prune theories. Theory pruning is defined as “hypothesis specification and study design intended to bound and reduce theory” (Leavitt et al., 2010, p. 644). A problem with organizational science was “the focus is on the support or lack of support for a single theory, with little attention to an alternative theory that could also describe the results” (Leavitt et al., 2010, p. 646). The same problem exists in educational leadership research as well. Over the last two decades from 1999 to 2018, a total of 483 theories had been used to frame empirical studies in educational leadership. Most of the educational leadership empirical research was designed to expand existing theories (e.g., add mediators or moderators) or to present new theories (e.g., teacher leadership and culturally responsive leadership).

Despite the value of research that expands existing theories and present new theories, the scant attention to theory pruning can be problematic in educational leadership research (Hambrick, 2007a, b) criticized this focus on expand existing theories and presenting new theories as “too much of a good thing” (p. 1346) and characterized this insistence on new theory as a “fetish” (p. 1350). Other scholars echoed this criticism. After analyzing 10 years of publications in *Organizational Research Methods* and the top 25 papers in management, according to citations, it was reported that very few papers tested competing theories (Aguinis et al., 2009). Among them, there was a paper that reconciled two opposing views about the effects of leaders at the top of organizational

hierarchy on organizational outcomes by introducing the construct of managerial discretion as a moderator (Finkelstein and Hambrick, 1990). One view, derived from strategic leadership, was that leaders at the upper echelons greatly influenced their organizational outcomes. The competing view, derived from institutional theory (DiMaggio and Powell, 1983), was that executives have little effect because organizations are exceedingly inertial and constrained by external and internal forces. Finkelstein and Hambrick argued that both views are conditionally valid, depending on how much managerial discretion—or latitude of action exists. Discretion exists when there is a limited constraint (e.g., a weak, passive board) and when there is a great deal of means-ends ambiguity—that is, when there are multiple plausible alternatives. In educational leadership, the limited attention to testing competing theories is glaring. Among the top five most highly cited educational leadership studies in each decade since 1960 (Hallinger and Kovačević, 2019), none of those studies put competing theories to test. However, “the greatest scientific value emerges when at least two models are specified representing competing conceptualizations and one emerges the strongest, especially over several replications” (Vandenberg and Grelle, 2008, p. 170).

Corroborating existing theories—without pruning inaccurate or ill-fitting theories—may contribute limited insights, hindering theory development in educational leadership. In the light of new empirical evidence, we can eliminate false theories (e.g., the earth is the center of the universe), correct false assumptions of existing theories (e.g., prospect theory correcting the false assumption of rational decision making in classic economics), and replace existing theories with more accurate ones. Most educational leadership scholars have taken a “confirmatory” approach, adding propositions to an ever-growing and expansive body of knowledge. Using empirical evidence to verify theories is indeed important for any field. However, it is equally important to use empirical findings to prune theory (Shareef, 2007). Theories are not static entities. Rather, they “are tentatively held, waiting to be disapproved or simply discarded for a variety of reasons and replaced by new conjectures” (Willower, 1980, p. 1). Eric Scerri, a philosopher of science, further elaborated on the evolving nature of theories: “One strength of science is that it is often wrong. It proceeds by overthrowing preconception, perhaps replacing misconceptions by a more sophisticated misconception until that misconception is replaced by yet another, until ultimately (we optimists all hope) arriving at some version of the truth” (p. x). To advance a field, researchers first conduct empirical research driven by theories. With new evidence emerges, some theories would undergo revision as more discoveries are made. Theories are then undergoing patchwork: they are altered, refined, fine-tuned, changed, or refuted with adjustments, but the general model remains. Consider social justice leadership and culturally responsive leadership. Also consider critical race theory and critical Latino theory. Once new theories are proposed, some researchers conduct empirical research to test the new theories, and others may be skeptical and propose a counter-argument. Over time, empirical evidence accumulates. If the accumulating evidence can be explained by the theories, then the theories survive. Otherwise, they are left in the dust, and the exploration of new theories marches on. An example in organizational science is that we no longer think of an organization has been organized into a closed system but into multiple dynamic systems.

If educational leadership researchers always confirm their priors, we fall into the prey of confirmation bias. To prune theories, it is important to ask: What findings do not stand up to the rigors of science? What are the assumptions proven wrong? Heaps of evidence may show the earlier theories could be on shaky ground. The trial-and-error process is the essence of science.

Conclusion

This article seeks to peek into the future of theoretical groundings in educational leadership research. To do so, I first discussed what theory is, and what theory is for. I then outlined the current theoretical groundings to set the stage for a forward-looking discussion. To catalyze the theory development in educational leadership, I provided two recommendations: refining definitions of theories and pruning theories.

Theory development—along with methodological advances—make theories and constructs ripe for empirical exploration, conceptual elaboration, theory pruning, and evaluative scrutiny. No theory is perfect. Do not slavishly believe all theories, or submissively accept all assumptions of the theories are correct. Challenge them. Argue against them. Find the evidence. Come up with your own theories. Allow your theories to be challenged by others. Allow your theories to evolve as the new evidence emerge. It is up to you to ensure the theory development in educational leadership. Feel free to use your intellectual prowess to challenge preconceptions and misconceptions in our field. An analogy is to see theories and constructs as the ingredients in your kitchen. Be innovative, put different ingredients together, and see how they interact and what they offer in the end. They might end up with something that makes you salivate, or something you cannot wait to throw into your trashcan. Nevertheless, you are trying to create something new. It’s part of the trial-and-error process in science.

That is a future worth working hard.

Introduction

The growth in the importance of school leadership over the past 20 years has been accompanied by theory development, with new models emerging and established approaches being redefined and further developed. The purpose of this article is to review current and recent writing on school leadership models. The article reviews theoretical literature, to see how leadership is conceptualized, and empirical literature, to demonstrate whether and how the research evidence supports these concepts of school leadership. It draws on UK and international school leadership literature.

The significance of school leadership

It is widely recognized that leadership is second only to classroom teaching in its impact on student learning. [Leithwood et al. \(2006\)](#) widely cited report shows that “leadership acts as a catalyst” (p. 4) for beneficial effects, including pupil learning. The report also distinguishes between the impact of headteacher leadership (typically 5–7%) and total leadership (27%). This finding provides much of the empirical underpinning for the current interest in distributed leadership (see below) and for the concept of leadership “density”.

[Robinson \(2007\)](#) meta-analysis of published research shows that the nature of the leader’s role has a significant impact on learning outcomes. Direct leader involvement in curriculum planning and professional development is associated with moderate or large leadership effects. “This suggests that the closer leaders are to the core business of teaching and learning, the more likely they are to make a difference to students” ([Robinson, 2007: 21](#)). This finding indicates that instructional leadership effects are much greater than those of other leadership models (see below).

[Leithwood et al. \(2006: 5\)](#) conclusion, that “there is not a single documented case of a school successfully turning around its pupil achievement trajectory in the absence of talented leadership”, offers powerful support for the vital role of principals, senior and middle leaders in all types of school.

Definitions of school leadership

[Gunter \(2004\)](#) shows that the labels used to define this field have changed from “educational administration” to “educational management” and, more recently, to “educational leadership”. [Bush \(2008\)](#) discusses whether such changes are purely semantic or reflect substantive changes in the nature of the field. [Yukl \(2002: 4\)](#) argues that “the definition of leadership is arbitrary and very subjective”, but the following “working definition” includes its main features:

Leadership is a process of influence leading to the achievement of desired purposes. Successful leaders develop a vision for their schools based on their personal and professional values. They articulate this vision at every opportunity and influence their staff and other stakeholders to share the vision. The philosophy, structures and activities of the school are geared towards the achievement of this shared vision

Bush and Glover (2003: 5).

Three dimensions of leadership arise from this working definition.

Leadership as influence

Most definitions of leadership reflect the assumption that it involves a social influence process whereby intentional influence is exerted by one person [or group] over other people [or groups] to structure activities and relationships in a group or organization (Yukl, 2002: 3). Bush (2008: 277) refers to three key aspects of these definitions. First, the central concept is influence rather than authority. Both are dimensions of power, but the latter tends to reside in formal positions, such as principal or head teacher, while the former could be exercised by anyone in the school or college. Leadership is independent of positional authority while management is linked directly to it. Second, the process is intentional. The person seeking to exercise influence is doing so to achieve certain purposes. Third, influence may be exercised by groups as well as individuals. This notion provides support for the concept of distributed leadership and for constructs such as senior leadership teams.

This aspect of leadership portrays it as a fluid process, potentially emanating from any part of the school, independent of formal management positions and capable of residing with any member of the organization, including associate staff and students

Bush (2008: 277).

Leadership and values

The notion of “influence” is neutral in that it does not explain or recommend what goals or actions should be pursued. However, leadership is increasingly linked with values. Leaders are expected to ground their actions in clear personal and professional values. Hargreaves (2004), drawing on research in Canadian schools, finds that teachers report largely positive emotional experiences of self-initiated change but predominantly negative ones concerning mandated change. There is a tension here between the obligation to implement the policies of democratically elected governments and the need for teacher professionals to feel positive about new initiatives if they are to act on them successfully.

Leadership and vision

Vision has been regarded as an essential component of effective leadership for more than 20 years. Southworth (1993: 23–4) suggests that heads are motivated to work hard “because their leadership is the pursuit of their individual visions” (Southworth, 1993: 47). Murphy and Torre (2015: 177) claim that “vision routinely surfaces in studies of effective organizations”, adding that it is “a hallmark component of every important school leadership framework (Murphy and Torre, 2015: 78). They scaffold vision to comprise three levels—mission, goals and expectations.”

The articulation of a clear vision has the potential to develop schools, but the empirical evidence of its effectiveness remains mixed. Thoonen et al. (2011: 520) refer to the “adverse effects” of vision, which arise when principals do not involve teachers in the process of vision building. Hoyle and Wallace (2005: 139) add that visions are expected to conform to centralized expectations.

A typology for leadership

There are many alternative and competing models of school leadership. In this section, we review eight of these models, drawing on Leithwood et al. (1999), and Bush (2020).

Instructional leadership

The increasing emphasis on managing teaching and learning as the core activities of educational institutions has led to “instructional leadership”, or “learning-centred” leadership, being emphasized. The term “instructional leadership” derives from North America and Hallinger (2019) traces its “transformation” from an American to a global leadership construct. He concludes that “effective instructional leadership results when leaders align both instructional and managerial roles with their personal values” (Hallinger, 2019: 32).

Instructional leadership is the longest established concept linking leadership and learning. However, several other terms may be used to describe this relationship, including pedagogic leadership, curriculum leadership and leadership for learning. Despite its prominence and longevity, instructional leadership has been criticized on two grounds. First, it is perceived to be primarily concerned with teaching rather than learning (Bush, 2013). The second criticism is that it “focused too much on the principal as the

center of expertise, power and authority" (Hallinger, 2003: 330), ignoring or underplaying the role of other leaders such as deputy principals, middle managers, leadership teams, and teacher leaders. Lambert (2002: 37) claims that "the days of the lone instructional leader are over. We no longer believe that one administrator can serve as the instructional leader for the entire school without the substantial participation of other educators". Hallinger (2019) historical analysis shows that instructional leadership has moved from being regarded as a singular function, exercised by the principal, to being conceptualized as a shared role, including middle and teacher leadership.

Instructional leadership focuses primarily on the direction and purpose of leaders' influence; targeted at student learning via teachers. There is less emphasis on the influence process itself. However, most other leadership models focus strongly on leadership processes. The discussion below focuses on models which mainly address "how" to lead, with less emphasis on the purpose of leadership.

Managerial leadership

Managerial leadership assumes that the focus of leaders ought to be on procedures, functions, and activities. Influence accrues largely because of the formal authority of leaders and Leithwood et al. (1999) argue that influence is allocated in proportion to the status of those positions in the organizational hierarchy. Leithwood et al. (Leithwood et al., 1999: 15) add that "there is evidence of considerable support in the literature and among practicing leaders for managerial approaches to leadership". They add that "positional power, in combination with formal policies and procedures, is the source of influence exercised by managerial leadership" (Leithwood et al., 1999: 17).

Gumus et al. (2018) review of educational leadership models shows the enduring influence of managerial leadership, linked to scientific management theory. They add that this model "may be more visible in those countries in which the education system is centralized, since it considerably emphasizes the implementation of practices mandated by higher external management authorities within the bureaucratic hierarchy" (Gumus et al., 2018: 29). Semarco and Cho (2018: 911) show that what they describe as "task-oriented managerial leadership behaviors" are common in Ghana, a centralized and bureaucratic education system. As noted earlier, a managerial approach to leadership does not necessarily obviate principals from also being effective instructional leaders (Hallinger, 2019).

Managerialism

The shift in the language of school organization to favor "leadership" at the expense of "management" is partly semantic, as noted above, but also reflects anxiety about the dangers of value-free management, focusing on efficiency for its own sake, what Hoyle and Wallace (2005: 68) describe as "management to excess":

Effective leadership and management "take the strain" by creating structures and processes which allow teachers to engage as fully as possible in their key task. Managerialism, on the other hand, is leadership and management to excess. It transcends the support role of leadership and, in its extreme manifestation, becomes an end in itself.

Managerial leadership is the model which provides the greatest risk of a managerialist approach to school organization. By focusing on functions, the aims of education may be subordinated to the managerial aim of greater efficiency. Simkins (2005: 13–14) claims that, in England, managerialist values, such as rigid planning and target-setting regimes, were being set against traditional professional values. Managerial leadership is an essential component of successful schools, but it should complement, not supplant, values-based approaches. Effective management is essential but value-free managerialism is inappropriate and damaging (Bush, 2020).

Transactional leadership

Transactional leadership relates to relationships between leaders and teachers being based on the exchange of valued resources. In its simplest form, teachers provide educational services (teaching, pupil welfare, extracurricular activities) in exchange for salaries and other rewards. Anderson and Chang (2019: 87) say that transactional leadership is "sometimes called leader-member exchange theory". Miller and Miller (2001) definition refers to transactional leadership as an exchange process while Judge and Piccolo (2004: 755) add that transactional leaders "focus on the proper exchange of resources". Interaction between administrators and teachers is usually episodic, short-lived, and limited to the exchange transaction.

Boocock (2019) reports on what he regards as transactional leadership in the English further education sector. He argues that successive governments have operated in a transactional mode, since colleges were incorporated in 1993. This takes the form of financial incentives to increase student enrollment. In addition, he claims that the Ofsted, the English inspection agency, encourages transactional leadership, notably through benchmarking in respect of student retention, achievement, and success rates, linked to a top-down inspection framework.

The major limitation of transactional leadership is that it does not engage staff beyond the immediate gains arising from the transaction and does not produce long-term commitment to the values and vision being promoted by school leaders. However,

Bass (1998: 11) stresses that leaders often use both transformational and transactional approaches. “Consistent honoring of transactional agreements builds trust, dependability, and perceptions of consistency with leaders by followers, which are each a basis for transformational leadership”. Oterkil and Ertesvag (2014) also claim that the best leaders are both transactional and transformational.

Transformational leadership

Transformational leadership is often contrasted with transactional approaches (e.g., Miller and Miller, 2001). This form of leadership assumes that the central focus of leadership ought to be the commitments and capacities of organizational members. Higher levels of personal commitment to organizational goals, and greater capacities for accomplishing those goals, are assumed to result in extra effort and greater productivity (Leithwood et al., 1999: 9).

The contemporary policy climate within which schools operate also raises questions about the validity of the transformational model, despite its popularity in the literature. Transformational language is used by governments to encourage, or to require, practitioners to adopt and implement centrally determined policies. In South Africa, for example, the language of transformation is used to underpin a non-racist post-Apartheid education system. The policy is rich in symbolism but weak in practice because many school principals lack the capacity and the authority to implement change effectively (Bush and Glover, 2016).

In certain centralized systems, governments may be seen to require school leaders to adhere to government policies, which affect aims, curriculum content and pedagogy, as well as values. In this respect, transformation may be a unilateral process of implementation, not a context-specific assessment of the needs of individual schools and their communities. Particularly significant is the raft of research on this model in highly centralized Arab countries, including the United Arab Emirates (Litz and Scott, 2017; Stringer and Hourani, 2016), Jordan (Khasawneh et al., 2012), and Kuwait (Alsaedi and Male, 2013). Litz and Scott (2017) stress the need to adapt the model to make it suitable for Arab contexts, notably the expectations around hierarchy and collectivism. They propose a “cross-cultural transformational leadership model” to reflect such expectations.

International research supports the notion that transformational leadership may produce beneficial effects. Thomas et al. (2020), for example, show that the principal’s transformational leadership was related to positive teacher attitudes, in their study of first-year primary school teachers in Flanders (Belgium). Similarly, Ninkovic and Floric (2018) indicate that transformational leadership had positive effects on collective teacher efficacy in Serbia.

The transformational model is comprehensive in that it provides a normative approach to school leadership which focuses primarily on the process by which leaders seek to influence school outcomes rather than on the nature or direction of those outcomes. However, it may also be criticized for its potential to become “despotic” because of its strong, heroic, and charismatic features. Allix (2000) believes that the leader’s power ought to raise “moral qualms” and serious doubts about its appropriateness for democratic organizations.

The transformational model stresses the importance of values but the debate about its validity relates to the central question of “whose values”? Critics of this approach argue that the decisive values are often those of government or of the school principal, who may be acting on behalf of government. Educational values, as held and practiced by teachers, may be subjugated to externally imposed values.

Moral leadership

The moral leadership model assumes that the critical focus of leadership ought to be on leaders’ values, beliefs, and ethics. Sergiovanni (1984: 10) says that “excellent schools have central zones composed of values and beliefs that take on sacred or cultural characteristics”, adding that “administering” is a “moral craft” (Sergiovanni, 1991: 322):

The school must move beyond concern for goals and roles to the task of building purposes into its structure and embodying these purposes in everything that it does with the effect of transforming school members from neutral participants to committed followers. The embodiment of purpose and the development of followership are inescapably moral.

Sergiovanni (1991: 323).

Gumus et al. (2018) claim that moral leadership requires several qualities, including holding to values, following ethical decision rules, and becoming a role model through visible moral actions. Keddie (2016: 724) research in two Queensland (Australia) schools leads her to address issues of equity and to conclude that “morally-focused leadership [is] concerned with more than increasing attainment on external measures of performance”. This links to the notion of “moral purpose”, illustrated in Rintoul and Goulais (2010) study of Ontario (Canada) vice-principals and in Bezzina (2012) research in New South Wales (Australia).

Moral leadership may have a spiritual dimension, especially in religious schools. Woods (1997: 148) survey of headteachers in England found that 52% “were inspired or supported in their leadership by some kind of spiritual power”. Gibson (2014: 531) study of leadership in secular New Zealand primary schools shows that “spirituality is a complex and controversial human phenomenon, the meaning of which may be shaped and re-shaped by diverse perspectives and experiences.... These characteristics were woven through the lived reality of the principals’ lives, through their beliefs, moral values, attitudes, and the quality of their

actions'. The author concludes that "spirituality in principle leadership is not one form of leadership but invites principals to integrate personal meanings of spirituality into their preferred leadership practice" (Gibson, 2014: 533).

Hammad and Shah (2019) report on the challenges of leading faith schools in a secular society, with specific reference to head teachers of four English Muslim schools. They note that Muslim schools with an emphasis on Islamic values appear to provide a "safe haven", where young Muslims are expected to grow as worthy members of the community. The challenges facing such heads include issues in developing Muslim identity in a secular society, recruitment of qualified Muslim teachers, and the expectations of their local communities. The authors conclude that supporting faith schooling is consistent with approaches such as integration, cultural pluralism, widening participation and celebrating diversity.

Sergiovanni (1991: 329) argues for both moral and managerial leadership:

In the principalship, the challenge of leadership is to make peace with two competing imperatives, the managerial and the moral. The two imperatives are unavoidable and the neglect of either creates problems. Schools must be run effectively if they are to survive.... But for the school to transform itself into an institution, a learning community must emerge... [This] is the moral imperative that principals face.

Distributed leadership

The models discussed above are essentially about individual (usually principal) leadership. However, there have been several approaches which seek to widen the debate to include shared approaches to leadership. Collegial and participative leadership were popular shared approaches in the 1980s and 1990s, but distributed leadership has become the normatively preferred leadership model in the 21st century. Gronn (2010: 70) states that "there has been an accelerating amount of scholarly and practitioner attention accorded [to] the phenomenon of distributed leadership".

Lumby (2019: 10) argues that "distributed leadership is not underpinned by a clear definition", adding that its "unique selling point" is the potential for "emergent spontaneous leadership" (Lumby, 2019). Hairon and Goh (2015) add that the construct of distributed leadership is elusive. Tian et al. (2016) systematic review of the literature also concludes that there is no clear definition.

An important starting point for understanding this phenomenon is to uncouple it from positional authority. As Harris (2004: 13) indicates, "distributed leadership concentrates on engaging expertise wherever it exists within the organization rather than seeking this only through formal position or role". She claims that it "is characterized as a form of collective leadership" (Harris, 2004: 14). Crawford (2012: 611) notes that interest in distributed leadership is part of a wider shift away from leadership as a solo activity. "This solo stance has been mediated by more prominence on shared leadership, variously described as democratic leadership, collegiality, participative leadership and distributed leadership". Gumus et al. (2018: 31) add that distributed leadership is often used interchangeably with shared, collaborative, delegated, and dispersed leadership.

Gronn (2010: 70) refers to a normative switch "from heroics to distribution" but also cautions against a view that distributed leadership necessarily means any reduction in the scope of the principal's role. Indeed, Hartley (2010: 271) argues that "its popularity may be pragmatic: to ease the burden of overworked headteachers". Lumby (2009: 320) adds that distributed leadership "does not imply that school staff are necessarily enacting leadership any differently" to the time "when heroic, individual leadership was the focus of attention". Referring to the South African context, Du Plessis and Heystek (2019: 3) ask whether there is sufficient "space for principals to practice distributed leadership in a traditional hierarchical system?". This point highlights the dilemma about how to accommodate distribution alongside solo leadership. Gronn (2010: 77) "hybrid" model of leadership may offer the potential to harness the best of both individual and distributed approaches.

The interest in, and support for, distributed leadership is predicated on the assumption that it will bring about beneficial effects that would not occur with singular leadership. Leithwood et al. (2006) important study of the impact of school leadership led to the articulation of "seven strong claims" about successful school leadership. Two of these claims relate to distributed leadership and Leithwood et al. (2006: 12) also show that multiple leadership is much more effective than solo leadership, explaining as much as a 27% variation in student achievement across schools, much higher than is typically reported in studies of individual headteacher effects. Hallinger and Heck (2010: 670) also found that distributed leadership was significantly related to change in academic capacity and, thus, to growth in student learning.

The contemporary popularity of distributed leadership is illustrated by the many studies influenced by this model. These include research with schools in England (Bush and Glover, 2012), schools in South Africa (Du Plessis and Heystek, 2019), rural primary schools in Ireland (Brown et al., 2019), Singapore schools (Hairon and Goh, 2015; Ho et al., 2016), Malaysian schools (Bush and Ng, 2019), early childhood in Finland (Kangas et al., 2016), and in Australia (Heikka et al., 2013), learning organizations in Sweden (Liljenberg, 2015), higher education in Australia (Jones et al., 2014), and in Finland (Vuori, 2019), and vocational education in the Netherlands (Bouwman et al., 2019). This extensive body of research offers a mixed picture of the value and impact of distributed leadership. However, there is some evidence that this model is being identified as the "label" for activities that might have been badged differently without the current interest in distribution. For example, Bush and Glover (2012) research with high performing school leadership teams shows that many leaders claim that their success is attributable to distributed leadership, but this was at a time when the English NCSL was advocating this model.

Allocative distribution

As noted earlier, distributed leadership is conceptualized as an emergent and spontaneous phenomenon in western literature (Bennett et al., 2003; Harris, 2013; Tian et al., 2016). However, the support for this model in centralized contexts has led to a different mode of distribution, with principals allocating tasks and responsibilities in a manner often indistinguishable from the management concept of delegation.

Bush and Ng (2019) examine the extent and nature of distribution in 14 schools in two Malaysian states, Selangor, and Sarawak. Distributed leadership features prominently in the country's main reform document, the Malaysia Education Blueprint. The advocacy of distributed leadership by the Malaysian Ministry of Education is recognition of its potential to enhance leadership density, and thus potentially to contribute to improved student outcomes. However, the Blueprint links distribution to the hierarchy in two ways. First, the focus is firmly on middle and senior leaders holding formal roles in the structure. Second, the scope of distribution is circumscribed; leaders will be prepared to fully utilize the decision-making flexibilities "accorded to them" (MEB: E28) (present authors' emphasis).

The Blueprint's cautious approach to distribution is consistent with the notion of allocative distributed leadership (Bolden et al., 2009). This suggests an uneasy compromise between the free-flowing assumptions of distributed leadership theory and the rigid requirements of the hierarchy. There is evidence of allocative distribution, predominantly to senior leaders, in most of the case study schools. The evidence from the Malaysian schools is that distributed leadership is almost indistinguishable from delegation because principals remain in control and have firm reporting requirements (Bush and Ng, 2019).

Hairon and Goh (2015) research on distributed leadership in Singapore leads them to discuss the related notion of "bounded empowerment". "It was obvious that empowerment in the Singapore context has a certain degree of 'restriction', hence bounded empowerment... empowerment in Singapore suggests the necessity to only relinquish control of decisions with certain caveats" (Hairon and Goh, 2015: 707).

Such restricted modes of distribution are not confined to centralized contexts. Holloway et al. (2018) discuss "prescribed" distributed leadership in the US, in the context of high accountable demands. They conclude that "highly prescribed leadership roles might help schools respond to external policy demands, but they do not necessarily nurture opportunities for leadership growth" (Holloway et al., 2018: 551).

These studies indicate that the language of distribution has been captured to legitimize practices previously described as delegation, contributing to critiques of this leadership model. Tian et al. (2016) meta-analysis includes a section called "questioning the concept of distributed leadership". One aspect of this critique relates to micropolitics, with Johnson (2019) warning that distributed leadership might be camouflaged as a micropolitical strategy to rationalize top-down management. Similarly, Lumby (2013) argues that distributed leadership is a political phenomenon "replete with the uses and abuses of power".

Lumby (2019: 11) offers a criticism which links to the earlier discussion of allocative distribution. "What appears to be happening resembles... formal and informal delegation within a bureaucratic system". She concludes that "the discovery of persistent hierarchy in sites where distributed leadership has been researched suggests that at least elements of bureaucracy are a near-universal approach to leadership" (Lumby, 2019: 14).

Teacher leadership

There are clear links between teacher leadership and distributed leadership. Frost (2008: 337) characterizes the former as involving shared leadership, teachers' leadership of development work, teachers' knowledge building, and teachers' voice. Grant (2006) offers a four-part model of teacher leadership, based on research in South African schools: leadership within the classroom, leadership beyond the classroom, with other teachers, leadership for whole-school development, and leadership beyond the school and in the community. She (2006: 523) adds that there are three prerequisites for teacher leadership: First, a collaborative culture is required, with participatory decision-making, and vision sharing. Second, a set of values is needed, to assist in developing the collaborative culture. Third, the principal and the formal management team need to encourage a distributed leadership approach.

Lai and Cheung (2015) examine teacher leadership in the context of curriculum reform in Hong Kong. They argue that teacher leadership has three distinct strands; participation, learning and influence, and they all require both teacher agency and support from senior leadership.

Developing teacher leadership may be particularly challenging in centralized contexts, for example in Egypt (Emira, 2010), where the Ministry of Education restricts teacher leadership to the classroom, and in Iran (Aliakbari and Sadeghi, 2014), where the education system is "top-down". However, Bush et al. (2016) research on master teachers as teacher leaders in Malaysia and Philippines shows that master teachers were able to operate at all four levels of the Grant (2006) model.

Stevenson (2012) argues that the interpretation of teacher leadership is managerialist in nature and inherently conservative. Helderbran (2010: 363) notes that teacher leadership "remains largely an academic topic and, even though inroads have been made, teacher leadership remains more a concept than an actuality". A culture of trust and collaboration is essential, as is a shared vision of where the school needs to go, clear line management structures and strong leadership development programmes'.

Contingent leadership

The models of leadership examined above are all partial. They provide valid and helpful insights into one specific aspect of leadership. None of these models provide a complete picture of school leadership. As Lambert (1995: 2) notes, there is "no single best

type". The contingent model provides an alternative approach, recognizing the diverse nature of school contexts, and the advantages of adapting leadership styles to the situation, rather than adopting a "one size fits all" stance.

Yukl (2002: 234) adds that "the managerial job is too complex and unpredictable to rely on a set of standardized responses to events. Effective leaders are continuously reading the situation and evaluating how to adapt their behavior to it". Leadership requires effective diagnosis of problems, followed by adopting the most appropriate response to the issue or situation (Morgan, 1997). This reflexive approach is particularly important in periods of turbulence when leaders need to be able to assess the situation carefully and react as appropriate rather than relying on a standard leadership model.

Notman (2017) study of two urban school principals in New Zealand shows the importance of the context in deciding leadership approaches. These leaders "were highly responsive to the demands and challenges within and beyond their own school context" (Notman, 2017: 768). The author concludes by stressing the need for contingent or "adaptive" leadership, sensitive to the school context, rather than a single inflexible model.

A contingent approach also helps to counter the normative features of many leadership models and responds to the tendency to advocate one "right" approach to school leadership. By recognizing that a range of approaches can be valid, it provides a more complete picture of leadership practice. The contingent model is pragmatic and is not underpinned by a clear set of values.

Conclusion: why leadership practices matter

The concept of management has been joined, or superseded, by the language of leadership but the activities undertaken by principals and senior staff resist such labels. Successful leaders are increasingly focused on learning, the central and unique purpose focus of educational organizations. They also face unprecedented accountability pressures in many countries in what is clearly an increasingly "results driven" business. As these environmental pressures intensify, leaders and managers require greater understanding, skill, and resilience to sustain their institutions (Bush, 2020).

Theory is one of the four essential building blocks of school leadership. Alongside policy, research, and practice, it provides helpful insights into how schools are led and managed. The theory of leadership is important for two main reasons. First, it provides a way of understanding and interpreting the actions of leaders. The models outlined in this article provide lenses to view and comprehend the ways in which leadership is enacted in schools. Second, understanding theory provides a guide to leadership practice for principals and other leaders. It widens horizons and avoids drawing only on the inevitably limited individual or collective experience of any single leader.

Each of the leadership models discussed in this paper is partial. They provide distinct but uni-dimensional perspectives on school leadership. They are also artificial distinctions, or "ideal types", in that most successful leaders are likely to embody most or all of these approaches in their work. For example, heads may aspire to develop distributed instructional leadership.

The importance of context has been increasingly acknowledged (Hallinger, 2018). This has several dimensions and there is a distinction between national contexts, with political, economic and social aspects, and internal school contexts, often conceptualized as organizational culture (Walker and Haiyan, 2019). Contingent leadership acknowledges the diverse nature of school contexts, and the advantages of adapting leadership styles to the situation, rather than adopting a "one size fits all" stance. It is not a single model but represents a mode of responsiveness which requires effective diagnosis followed by careful selection of the most appropriate leadership style. It is pragmatic, rather than normative, unlike most of the other leadership models (Bush, 2020).

Leadership practices matter because of the evidence that effective leadership enhances student learning and school improvement (Leithwood et al., 2006). There is also a body of research showing that certain models may be particularly effective in raising student outcomes. The Leithwood et al. (2006) study, for example, shows the potential of distributed leadership. "School leadership has a greater influence of schools and pupils when it is widely distributed" (Leithwood et al., 2006: 12). In contrast, Robinson (2007) meta-analysis indicates that instructional leadership has more impact on student learning than other leadership models. Transformational leadership also has its advocates because of its potential to inspire greater commitment from teachers and other stakeholders.

The shifting popularity of different leadership models leads to consideration of the nature of theory in educational leadership. To what extent is it a representation of practice (description), and to what extent does it constitute advocacy; a normative perspective? Distributed leadership is the most recent model to be subject to a strongly normative approach; "the theory of choice for many" (Lumby, 2013: 581). Gunter et al. (2013) criticize the normative approach to distributed leadership. "Normative work tends to present the idea of distributed leadership as an imperative for practitioners as school improvers... the normative approach tends to have rationales that are based on exhorting how and why distributed leadership should be adopted" (Gunter et al., 2013: 563).

Lumby (2013: 582) comments that discussion of distributed leadership as a heuristic tool gave way to an evangelical approach, for example by the English National College for School Leadership (NCSL). This may explain, in part, the frequent references to distributed leadership by participants in a study of senior leadership teams at schools rated as "outstanding" by Ofsted (Bush and Glover, 2012). Unprompted, these leaders attributed their perceived success to adopting distributed approaches.

A normative approach to leadership theory, by academics, practitioners, or policy makers, is not new. Bureaucracy, collegiality, transformational leadership, and instructional leadership are also treated in this way. This suggests that leadership is over-theorized and under-researched.

The leadership typology discussed in this article provides many clues for heads, senior and middle leaders, and senior leadership teams. Managerial leadership, operating through the hierarchy, can mandate clearly targeted change, such as a stronger focus on examination and test scores. However, this often depends on a single leader and may not lead to sustainable change. Transformational

leadership approaches aim to widen commitment to school-wide objectives, through the development of shared vision, but the “vision” is often that of the head or principal with acquiescence, rather than genuine commitment, from teachers and other staff.

The limitations of the hierarchy have led to a plethora of alternative models, including distributed and teacher leadership, which are designed to broaden leadership and to stress lateral as well as vertical relationships. These are often manifested in team-based structures. [Bush and Glover \(2012\)](#) study of high performing senior leadership teams showed their value in providing coherence and leadership “density”.

While there are different approaches to leadership and management, recognition of the need for clear direction-setting, linked to moral purpose, is likely to be helpful in enhancing school leadership, for the benefit of pupils and students.

Introduction

This article synthesizes what is known about transformational leadership in school settings from previous reviews of such research (Chin, 2007; Leithwood et al., 1996; Leithwood and Jantzi, 2005; Leithwood and Sun, 2009, 2012; Sun and Leithwood, 2012), as well as from additional quantitative journal articles and dissertations reported in the past 10 years not included in previous reviews. The new evidence includes 99 dissertations from the ProQuest Dissertation database and 33 journal articles from the Eric-ProQuest Database, *Review of Educational Research* and the following eight major journals in the field of educational leadership: *Educational Administration Quarterly*, *Journal of School Leadership*, *Journal of Educational Administration*, *Leadership and Policy in Schools*, *International Journal of Leadership in Education*, *International Studies in Educational Administration*, *Educational Management, Administration and Leadership*, and *School Effectiveness and School Improvement*.

In order to be included in this review, a study must have been quantitative, empirically examined transformational leadership in school settings and reported a correlation between transformational leadership and at least one outcome variable. While this additional evidence may not be exhaustive, it does represent a sizable amount of research on transformational leadership in schools. Due to limited space, some of the new evidence providing background for the article is not included on the reference list.

The remainder of the article highlights the origins and development of the concept of transformational leadership (TL), identifies its typical practices, and reports the impact of TL on schools, teachers, and students. TL impact was estimated using vote-counting methods and the averaging of correlation coefficients or effect sizes. This article concludes with suggestions for future research.

The origin and major developments of transformational leadership

Transformational leadership was initially conceptualized by Burns (1978), in response to researcher and practitioner skepticism about inquiries into leadership effectiveness. Burns defined the purpose of leadership as exercising influence on followers to work toward transcendental goals instead of immediate self-interest and toward achievement and self-actualization instead of safety and security. Scholars from the traits, behavioral, and contingency schools of leadership had tried to find associations between leaders' traits and behaviors (especially contingent behaviors) in different contexts with varying levels of organizational effectiveness (Day and Antonakis, 2012), but these studies yielded mixed results.

Since the 1970s, the conception of TL has undergone major developments, including, for example, Kouzes and Posner's (1995) Leadership Practices Inventory (LPI) framework, Sashkin's (2004) conceptualization of transformational leadership as encompassing a leader's own behaviors, characteristics, and culture-building efforts, and Tichy and Devanna's (1990) three-act play of redesigning organizations. In non-educational contexts, the model of transformational leadership has been developed in its most mature form by Bass and his associates (e.g., Bass, 1985; Bass and Avolio, 1994). They developed a "two-factor theory" along with the Multifactor Leadership Questionnaire (MLQ) to measure transformational leadership. According to Bass and Avolio, transformational and transactional leadership are two separate ends of a continuum. Most leaders do some of both, but transformational leadership has augmented effects above transactional leadership.

While Burns saw an upward shift in the level of followers' needs as fundamental to the process of transformation, Bass (1985) suggested that the expansion of needs on the same level or even a downward shift could also be evidence of a transformation though he acknowledged that in the world of work, transformational processes usually involve the upgrading of needs. Bass also argues that in the process of transformation the change can be either good or bad, and that transactional leadership is a necessary component of transformational leadership. Bass and his colleagues placed more emphasis on the characteristics of leadership practices and their influential outcomes, rather than on the nature and the power of moral elevation of this type of leadership, when they formulated the two-factor theory of transformational leadership (Bass and Avolio, 1993).

The origin of the concept of transformational leadership is also associated with Weber (1922; 1947) coining of "charisma" from the Greek, meaning "divine gift." He defined charismatic leaders as those who use their considerable emotional appeal to direct their followers. Many scholars thereafter incorporated charisma as one of the most important components of transformational leadership. This component, as well as ideas about the "leader-hero" in some conceptualizations of transformational leadership led to critiques about the dark side of transformational leadership. Such critiques were about the ideological nature of "self-centered" "leader hero", excessive positivity, and emotional appeals to those who follow and make extra commitment without good reasons (Alvesson and Einola, 2019; Yukl, 1999). Proponents of transformational leadership (e.g., Bass and Steidlmeier, 1998), argue that true transformational leadership must be grounded in moral foundations to avoid the dark side of charismatic leaders.

The birth of transformational school leadership (TSL)

Transformational leadership was introduced into the education field in the early 90s (Hallinger, 1992; Leithwood, 1992, 1994). Leithwood and his colleagues modified and adapted earlier versions of transformational leadership (e.g., Podsakoff et al., 1990) to better suit the leadership demands found in schools and developed TSL to its fullest form over a number of years (e.g., Leithwood, 1992; Leithwood and Jantzi, 1990; 1999, 2005; Leithwood and Steinbach, 1991; Leithwood et al., 1996; Leithwood and Sun, 2009). Their most recent version (Leithwood, 2017; Leithwood and Jantzi, 2005; Leithwood and Sun, 2012; Leithwood et al., 2004) conceives of transformational leadership as including five broad categories of practices including a total of 21 specific practice: *Setting Directions*, *Developing People*, *Redesigning the Organization*, *Improving the instructional program*, and *Managing and Securing Accountability*. With the addition of *Improving the Instructional Program*, Leithwood's model of TSL became an integrated model (a combination of instructional and transformational leadership). While incorporating typical elements of other transformational leadership models developed for non-educational settings and integrating them in the first three domains, Leithwood's model of TSL was expanded to acknowledge the importance of attending to the technical core of schooling and incorporated practices central to instructional leadership. Further, unique leadership practices that support instruction in schools, such as those developing shared school goals and holding high expectations, improving school environment and instructionally helpful school culture, developing teachers, engaging communities, and building collaborative structures, were additions to each of the first three domains. None of these practices are included in TL models developed in non-school settings, or in most of the other TSL models.

The Ontario Leadership Framework (OLF) (Leithwood, 2012), built upon Leithwood's early versions of TSL, includes a full range of transformational school leadership elements. Hitt and Tucker (2016) claim that this is the most comprehensive effective school leadership framework currently available. This framework includes both transformational and instructional leadership practices, guidelines about how, where and when to enact those practices, as well as Personal Leadership Resources (cognitive, social, and psychological resources known to improve leader effects). A revision of the framework currently underway awards greater attention to leaders' ethics and values. Embedded in this integrated model are the most important elements of school leadership reported in the past three decades of research conducted from several major approaches, or schools of leadership theories, including, for example, trait theory (e.g., self-efficacy, emotional intelligence), motives and values, cognitive abilities, social and

problem-solving skills and expertise of leaders, information-processing theory, instructional leadership, transformational leadership, distributed leadership, inclusive leadership, and contextual school of leadership (see Antonakis et al., 2012 for short descriptions of these schools of leadership theories). Thus, OLF, the most fully developed TSL model developed to date, addresses the main critiques of earlier versions of transformational leadership such as the emphasis on the leader-hero, lack of consideration of the context the leader works in and with, and the ambiguity of leadership behaviors. While earlier studies in educational contexts tended to use Bass's MLQ to measure transformational leadership in schools, more recent studies in schools have tended to use Leithwood's survey.

Typical models and practices of transformational leadership

Over the past 35 years, twelve models have been used by researchers to examine and measure transformational leadership in schools (Leithwood and Sun, 2012; Sun, 2016). Three of these models were developed from evidence originally collected in non-educational settings including:

- Bass and his associates' two-factor theory measured using the Multifactor Leadership Questionnaire (MLQ) (Bass and Avolio, 1989, 1991, 1995, 2004, 2004; Avolio and Bass, 1999, 2004) and their adaptations (e.g., Edwards et al., 2010)
- Kouzes and Posner's (1993, 1995) Leadership Practices Inventory (LPI)
- Sashkin's visionary leadership measured by the Leadership Behavior Questionnaire (LBQ) (1990)

Nine transformational leadership models were developed specifically for educational settings, Leithwood's model is the most inclusive and most frequently used model, with the other eight only used in one or few studies each.

- Leithwood's TSL model measured by the Principal Leadership Questionnaire (PLQ) (e.g., Leithwood and Jantzi, 1991; 1997; 1999; 2006; Jantzi and Leithwood, 1996), early versions of the Nature of School Leadership survey (NSL) (Leithwood et al., 2001), more recent versions (Leithwood et al., 2006a,b; Leithwood, 2017), or adapted version (Day et al., 2016; Starks, 2018)
- Transformational leadership adapted to Dutch contexts (Geijsel et al., 2003; Thoonen et al., 2011; 2012 cited in Moolenaar and Sleegers, 2015; Moolenaar et al., 2010; Vermeulen et al., 2015)
- Three studies (Kuan, 2020; Huang and Hsieh, 2010; Urlick and Bowers, 2014) selected items from other school leadership surveys to measure transformational leadership
- Principal's Transformational Leadership Questionnaire (Chong-Hee No, 1994 in Ham 1999)
- Three author-constructed transformational leadership instruments (Perkins, 2018; Showalter, 2016; Wiley, 1998)

School leadership practices involved in these twelve models used in the original studies were synthesized into 13 practices (a practice is a set of leadership activities). These 13 practices, described further below, can be grouped into five categories: Setting Directions, Developing People, Redesigning the Organization, Improving Instruction, and Managing and Securing Accountability.

Setting directions

Developing a shared vision and building goal consensus

This dimension involves leadership practices that identify, develop, and articulate a shared vision that is appealing and inspiring to staff. It also includes practices related to achieving goal consensus among staff, motivating staff with challenging while achievable goals, giving staff an overall sense of purpose for their work, and monitoring and referring to school goals when staff are making decisions.

Holding high performance expectations

Holding high performance expectations means that leaders expect a high level of professionalism from staff, hold high expectations for students, and expect staff to be effective innovators (Leithwood et al., 2006a,b).

Developing people

Modeling behavior

The leadership practices involved in the various conceptualizations of modeling behavior include leaders walking the talk, providing a role model for highly ethical behavior, instilling pride, respect, and trust in staff, symbolizing success, and demonstrating a willingness to change their own practices as a result of new understandings.

Providing intellectual stimulation

The practices included in this dimension are leaders challenging staff's assumptions, stimulating and encouraging their creativity, and providing information to staff to help them evaluate their practices, refine them, and carry out their tasks more effectively.

Providing individualized support

This practice dimension involves leaders listening and attending to individual opinions and needs, acting as mentors or coaches to staff members, treating them as individuals with unique need and capacities, and supporting their professional development.

Redesigning the organization***Strengthening school culture***

The leadership practices related to strengthening school culture are leaders promoting an atmosphere of caring and trust among staff, building a collaborative school culture that reflects the school vision, and encouraging ongoing collaboration for program implementation.

Building collaborative structures

Building collaborative structures involves leadership practices that ensure that staff have adequate involvement in decisions about programs and instruction, establish working conditions that facilitate staff collaboration for planning and professional growth, and distribute leadership broadly among staff (Leithwood et al., 2006a,b). This dimension of leadership was mainly developed in Leithwood's model of TSL.

Engaging communities

Engaging communities was conceptualized and included only in Leithwood's model of TSL. The practices related to this dimension include leaders demonstrating sensitivity to community aspirations, diversity, and requests, incorporating community characteristics and values in the school, and actively encouraging parents and guardians to become involved in their children's education (Leithwood et al., 2006a,b).

Improving instruction***Focusing on instructional development***

Focusing on instructional development was conceptualized in both Leithwood's and Willey's models of TSL. It involves a broad range of leaders' practices related to planning and supervising instruction, providing instructional support, frequent and regular monitoring of school progress, and buffering staff from district or state initiatives that are potential distractions from school priorities. The development and inclusion of this dimension of leadership is a significant advancement or departure for transformational school leadership from the business sector where Bass' model was originally developed.

Managing and securing accountability***Contingent reward***

Contingent reward means that the leader rewards the follower for completing the agreed-upon work.

Management by exception

This leadership practice occurs when the leader monitors the performance of the subordinate and interferes when this performance deviates from the norm.

Providing resources

In this practice, the leader provides resources to teachers and schools to facilitate instruction, foster teacher professional development, and meet the needs of students.

Securing accountability

The OLF (Leithwood, 2012, 2017) expands the leadership model's attention to a broad policy context which holds most school leaders accountable for advancing their schools' achievement of widely valued student outcomes. This practice also includes leaders' efforts related to a supervisory and monitoring role in teaching and learning for quality assurance and accountability and managing staff (Kwan, 2020). A more detailed description of the early version of these TSL practices can be found in Leithwood (2010).

The impact of transformational leadership on school conditions

Evidence reviewed in this paper examined the effects of transformational leadership on 19 school organizational outcomes. There are significant numbers of analyses about the effects of transformational leadership on three of these school characteristics with smaller amounts of evidence about an additional 16 characteristics. Of those conditions for which there is significant evidence, Organizational Culture and Climate has been studied most (34 analyses), followed by Shared Goals and Mission (7 analyses) and Shared Decision making (6 analyses). Results indicate moderate to large effects of transformational leadership on these school

conditions. Transformational leadership appears to be most effective in achieving shared goals and nurturing cohesiveness and collaboration within schools.

This evidence demonstrates the strong contribution of transformational leadership to conditions that enable teaching and learning. Most of the individual transformational leadership practices have significant positive effects on some school conditions suggesting that transformational leaders' effects may depend on the enactment of as many of the TSL practices as possible.

The impact of transformational leadership on teachers

Evidence reviewed for this paper examined the effects of transformational leadership on 25 teacher characteristics, states or dispositions. There are significant numbers of analyses about the effects of transformational leadership on four of these characteristics or dispositions with smaller amounts of evidence about an additional 21. Of those teacher dispositions for which there is significant evidence, Teacher Commitment and Work Engagement has been studied most (31 analyses), followed by teachers' Job Satisfaction (25 analyses), Teachers-Perceived Leader Effectiveness (14 analyses), and teacher self-efficacy (11 analyses). Results indicate large effects of TSL on the first three teacher outcomes and moderate effects on teacher efficacy. TSL appears to be very influential in prompting positive individual perceptions of leaders and improving individual psychological states. This finding is generally consistent with the theory of transformational leadership conceptualized by Burns' (1978), in which the influence of transformational leadership is the elevation of motivation and morality in both the leader and followers, resulting in subordinates being motivated by the leader's vision and heightening their efforts to achieve that vision. This observation is also consistent with previous reviews (Leithwood and Sun, 2009, 2012; Leithwood and Jantzi, 2005; Chin, 2007). The large impacts of individual transformational leadership practices often arise from principals' building a shared vision, providing intellectual stimulation and individualized support, and modeling behaviors (Leithwood and Sun, 2012).

The impact of transformational leadership on students

A much smaller but growing number of studies have examined the impact of transformational leadership on students, compared with those on teachers and school conditions. Only one or few studies have examined the (mostly non-significant) effects of such leadership on attendance, college-going rates, drop-out rates, engagement, modernity, or graduation rates (e.g., Leithwood and Jantzi, 2000a,b; Wang, 2019). In contrast, 32 studies have examined the impact of transformational leadership on student achievement. While earlier studies directly measured the direct effects (relying on correlations) of transformational leadership on student achievement, more recent studies have examined the indirect effects of such leadership on student learning. This approach reflects the consensus that has been reached in the last 10 years in the field of educational leadership that school leaders' impact on student learning outcomes is largely indirect (Hallinger and Heck, 1996; Heck and Hallinger, 2014; Leithwood et al., 2004; Leithwood and Louis, 2012). A central challenge for this line of research is to locate potentially powerful mediators of leaders' effects on students and determine how leaders' can positively influence the status of those mediators. Studies addressing this challenge have used complicated statistical methods such as Structural Equation Modeling and regression mediation and/or moderation. The next section summarizes the results of research examining the direct and indirect effects of TSL on student achievement.

Direct effects of transformational school leadership on student achievement

Transformational leadership had small but significant, positive direct effects on student learning based on a meta-analysis of 24 dissertations (Leithwood and Sun, 2012). Separate meta-analyses of TSL's impact on student learning in reading and math yielded the same results. New evidence reviewed for this paper (published in eight major journals in educational leadership and *Review of Educational Research*) was consistent with this earlier evidence. These results also reflect the results of other studies and meta analyses examining the effects on students of diverse leadership models (Brown, 2001; Waters et al., 2010; Witziers et al., 2003). Chin's (2007) review of unpublished research on the effects of transformational leadership on student learning found an effect size (weighted mean r) of .49, higher than was found in our own meta-analysis of unpublished research (Leithwood and Sun, 2012).

While evidence supports the significant effect of transformational leadership on student achievement, Robinson and her associates' study (Robinson et al., 2008) report stronger effects for instructional as compared with transformational leadership. While their study reported a relationship of $ES = 0.11$ between transformational leadership and student outcomes, the average effect of instructional leadership on student outcomes was three to four times that size. It is difficult to make comparisons of the findings of our study with Robinson and colleagues for several reasons: the unknown nature of their study's mean effect sizes; the effect size calculation procedure they used, and the significance and homogeneity analysis of the effect sizes. That said, Robinson et al.'s (2008) study revealed strong average effects on student outcomes for the leadership dimensions involving promoting and participating in teacher learning and development and moderate effects for the dimensions concerned with goal setting and planning, coordinating, and evaluating teaching and curriculum, all of which are leadership practices included in Leithwood's model of transformational leadership and measured, for example, in the NSL (Leithwood et al., 2001). The impact of instructional and transformational types of leadership on student outcomes did not differ significantly in Brown's (2001) study ($d = .62, .74$).

Subsequent research about the effects on students of more fully conceptualized models of transformational leadership will no doubt clarify the relative and absolute effects of transformational leadership on students' learning. However, the practical answer to questions about relative effects is likely to reside in the development of leadership models that integrate practices associated with both instructional and transformational approaches. As Marks and Printy (2003) argue, it would be more fruitful for future research to develop such models and to identify individual leadership practices that are effective in improving student learning. Of the 13 transformational leadership practices summarized in the previous section (an integrated model of transformational leadership), Building Collaborative Structures and Providing Individualized Support are the most influential sets of practices; their direct effects are significant but small with weighted means r ranging from 0.15 to 0.17. (Leithwood and Sun, 2012).

Indirect effects of transformational leadership on student achievement

With school leadership effects now widely understood to be indirect, a growing number of studies have inquired about those variables which significantly mediate leadership effects. These are variables with more or less direct effects on students whose status can be influenced by leaders. These studies have approached indirect leadership effects by incorporating, in their research designs, (a) only mediating variables, (b) both mediating and moderating variables, or (c) only moderating variables.

The mediating variables that were included in the first group of studies were teacher collective efficacy, teacher commitment, professional community, teacher efficacy, teacher empowerment, shared school mission, and teacher job satisfaction. Among these mediators, most of these studies found that collective teacher efficacy and teacher commitment were positively and significantly related to student achievement. Studies conducted earlier using regression (e.g., Ross, 1998; Floyd, 1999) often reported a non-significant impact of transformational leadership on student achievement when mediators were put into the equation. These results suggest that the impact of transformational leadership on student learning is mostly indirect, and through mediators.

The several studies of transformational leadership effects on students that included both moderating and mediating variables reported generally larger effects than were reported in studies with simpler designs. Solomon's (2007) study, for example, reported a very large regression total R of .79 between transformational leadership, teacher commitment, teacher collective efficacy, SES, and student achievement. The effects of transformational leadership on student achievement seemed contingent upon which moderating and mediating variables were taken into account. As a second example, Nicholson's (2003) study in 146 Ohio elementary schools examined the influence of transformational leadership on student achievement as mediated by teacher collective efficacy. Teacher collective efficacy was positively related to student achievement even when controlling for SES and prior achievement. This study did not find a significant association between transformational leadership and collective teacher efficacy. However, structural equation modeling demonstrated that the transformational leadership practice of "intellectual stimulation" was directly related to math achievement; this relationship was not mediated by teacher collective efficacy. Future research that identifies the most important mediators that improve student learning effectively, and the transformational leadership practices and contextual factors or moderators that work best to improve the status of these mediators, would be very useful. Such combinations of TSL practices, mediating variables and contextual factors would uncover important contextualized paths through which transformational leadership improves student learning.

Conclusions

This synthesis of research on transformational school leadership demonstrates significant progress in clarifying the meaning and effects of this approach to leadership. Developed by many groups of scholars over decades, the various versions of transformational leadership, especially Leithwood and his colleagues' model (Leithwood et al., 2006a,b), subsume instructional and managerial forms of leadership (see the Improving the Instructional Program dimension of transformational leadership in Leithwood et al., 2006a,b for an example), ground its roots in moral foundations (see Bass, 1997; Bass and Steidlmeier, 1998 for detailed arguments), and can be participative (Bass, 1997; Channell, 2015; Thomas et al., 2020). About twelve versions of transformational leadership have guided research in school contexts. This research has examined transformational leadership effects on about 19 school outcomes, 25 teacher outcomes, and six student outcomes. Empirical research on transformational leadership in school settings has been gradually addressing the critiques of transformational leadership as promoting a "heroic" view of leadership, being excessively positive and paying insufficient attention to negative effects, being ambiguous about transformational behaviors and underlying influence processes, as well as overemphasizing dyadic processes, and (Alvesson and Einola, 2019; Yukl, 1999). That said, there are, however, at least five gaps in such progress that warrant future research. First the majority of studies were focused on a few school, teacher and student outcomes. Much more research is needed to clarify TSL's influence process on these and other outcomes.

Second, the development of transformational leadership in educational contexts has absorbed and integrated many other leadership models, a goal considered worth pursuing by a number of scholars (e.g., Antonakis et al., 2004; Hunt, 1999). The concept of TSL entails transforming teaching and learning in schools, as well as the school as an organization. Most studies of transformational leadership effects to date, however, have been based on narrow conceptions of transformational leadership (e.g., Bass and Avolio, 1995), conceptions that do not acknowledge leaders' organizational contexts and efforts to improve instruction in schools. For this reason, most studies have failed to identify or report the "real" impacts of TSL on school, teacher, and student outcomes. Especially

those instruction-related practices aimed at improving student learning need to be addressed with additional research. Future research should adopt versions of TSL that includes a broader range of practices suitable for school contexts and examine especially those TSL practices related to instruction and community building.

Third, the majority of studies have treated transformational leadership as a whole. It remains for future research to identify the relative contributions of individual TSL practices to improving school, teacher, and student outcomes. Three meta-analyses (Sun and Leithwood, 2012, 2015, 2017) illustrate the value of such research to date. For example, these reviews found that Direction-setting leadership practices (DSLPS), in aggregate, are effective in shaping a positive working environment and culture, achieving shared understanding of school goals among staff, and fostering shared decision-making in schools. Specifically, transformational school leaders' efforts to develop a shared vision in schools mostly influences teachers' individual internal states, especially teachers' judgment of leadership effectiveness and teachers' job satisfaction. School organizations with a shared vision motivate teachers to commit to and make extra efforts (Organizational Citizenship Behavior) toward that vision. DSLPs alone are not effective in building teachers' trust in school organizations. DSLPs have small and moderate impacts on improved instruction and teacher utilization of knowledge, and a close-to-large impact on various cultural outcomes.

Fourth, future research should aim to identify the critical paths or mediators through which individual transformational leadership practices have their effects on school conditions or teacher dispositions, which in turn improve student learning. Such an approach, adopting a broad range of TSL practices, would better estimate the overall impact of TSL on student learning. Using more sophisticated research methods, such as Structural Equation Modeling incorporating both important mediating and moderating variables, would uncover much more of the contextualized critical paths through which TSL improves student learning, and thus yield much more useful information to practitioners and policy makers.

Finally, more research should aim to understand what gives rise to TSL. Compared with inquiry into the nature and impact of transformational leadership, evidence about factors that give rise to TSL (the antecedents of TSL) is relatively sparser. Only two previous reviews (Leithwood and Jantzi, 2005; Sun et al., 2016) have touched on this problem. This very limited evidence identifies several predictors of TSL practices – principals' efficacy beliefs, values, formal training and emotional intelligence. Findings from this line of research can inform leadership preparation programs, the development of transformational school leaders and appointment of principals in different school contexts.

Introduction

This article provides a critical synthesis of what selected research has shown internationally about who effective and successful school leaders are and what they do in order to achieve and sustain success in a range of school contexts, within and across national jurisdictions. It focuses on the most significant models, frameworks and pathways, and international research projects identified by researchers as furthering understandings of leadership, differentiating between those who are “effective” and “successful”. Alongside this, the article highlights the importance of acknowledging the influence of broader national cultures, and the need to understand schools as complex adaptive systems.

With few exceptions, research on school effectiveness and improvement has found that who school leaders are, what they do, and how and when they do it matters, and makes a significant difference to school culture, teacher motivation, quality, retention, and student learning, achievement and wellbeing trajectories. A range of research internationally has shown that high quality school leadership is second only to classroom teaching as a direct influence on pupil learning (Leithwood et al., 2006), and that it contributes, albeit mostly indirectly, through establishing key school conditions, and influencing the values, dispositions, aspirations, expectations, and practices of teachers (e.g., Day et al., 2000; Heck and Hallinger, 1999, 2014; Leithwood and Seashore-Louis, 2012; Marzano et al., 2005; Robinson et al., 2008). Because teachers are key contributors to student learning, achievement, and wellbeing, school leadership is most effective when it improves or sustains their curriculum knowledge, classroom skills, commitment, capabilities for change and development, active engagement, and capacity for resilience. However, just as research has shown that there are variations in teachers’ work, lives and effectiveness, so the same applies to the work, lives and effectiveness of school leaders. This article will focus on what research internationally has shown about who effective and successful school leaders are, what the similarities and differences between them are, and what they do in order to achieve success. It will also discuss strengths and limitations of research methodologies.

A brief history of leadership research

Research on school leadership in the mid 20th century was dominated by psychological paradigms and business leadership writers. Early research derived from these perspectives identified broad types of leadership, for example, “authoritative”, “democratic” and “laissez faire” leadership (Lewin et al., 1939). Later, leadership personality “traits”, and “styles” were identified. “Charismatic” and “heroic” leadership were identified as important (Parry and Bryman, 2006). Later, contrasting models comparing “transformational” with “transactional” leadership, derived from research on businesses by Burns (1978) also became popularized (e.g., Bass, 1985; Bass and Avolio, 1994). Over the last three decades especially, there has been an upsurge of researcher interest in school leadership. This coincided with the rise of new “neoliberal”, results-driven agendas in the public services in which teaching

and learning in schools have become more transparent, and school leaders have more accountability for raising the academic levels of attainment of all students, and alongside this, attending to their social and personal wellbeing. As “audit” cultures of external monitoring and evaluation became embedded (Power, 2019) a by-product of societies in which levels of trust in society and teachers in particular diminished, policy makers began to intervene in education more actively in order to solve challenges of international economic competition and social fragmentation. Researchers internationally began to conduct much more empirically grounded, nuanced portraits of “effective” and “successful” school leaders, and much of this found that previous research findings were less relevant to the increasingly complexities of school leadership and management in this century (Northouse, 2013).

Although this concentration of research has increased exponentially, educational researchers’ unprecedented interest in and pursuit of the “best,” most “effective” school leadership can be dated back to the Effective Schools movement in North America and the UK in the 1970s. In response to the assumption that schools have little effect on student achievement (e.g., James and Coleman, 1968; Jencks et al., 1972), researchers identified about a dozen essential qualities of effective schools, where students of all backgrounds, regardless of socio-economic status or family background, were successfully educated. They claimed that among those factors necessary to student success that schools can control is *effective* school leadership (Purkey and Smith, 1983; Downer, 1991; Sammons et al., 1995).

The school effectiveness movement emphasizes the importance of school leadership for the improvement of student outcomes. This ideal for those who seek to make a difference as educational leaders. However, school effectiveness research potentially ignores the complexity of school culture, narrowly conceptualizing pedagogy as a set of homogenous teaching techniques that can be applied in a range of school cultures (Hattie, 2009), rather than seeing pedagogy as a holistic educational act that is purpose driven and takes into account student diversity and different school cultures and values (Alexander, 2008). As Alexander (2008) explains:

Teaching is presented as value-neutral, content free and entirely devoid of the dilemmas of value and circumstance that confront real teachers daily. It conceals the technical deficiencies of the research and implies a degree of homogeneity in schools, classrooms and lessons that cannot be sustained empirically (p. 31).

Successful leadership literature has provided answers for educational leaders beyond the school effectiveness movement, in that it assumes that student outcomes represent more than measured academic attainment; that these are related to the quality of teachers and teaching and that the quality of school leadership is key (Pont et al., 2008). Research shows that while teacher effectiveness does not necessarily depend directly on the effectiveness of the principal, principal vision, values, structures, cultures and relationships make a difference. (Robinson et al., 2008; Day, 2017).

Stemming from the original work on effective schools, which pointed to the pivotal role of designated leaders, an increasing, if diverse, flow of research subsequently emerged, principally in Western nations, with school principals as the chief focus of interest. This now incorporates both psychologically and sociologically oriented research, as researchers recognized the importance of the social contexts as an influencing factor in schools which have become “policy mediators”, and, within this, the pivotal role of principals. So many “models” emerged that one Australian researcher remarked that the “myth” of individualism (typified by “charismatic” and “heroic” leadership descriptors) was being perpetuated:

Within the literature on school leadership there also remains an overwhelming endorsement of one-style-fits-all leadership, often accompanied with varying degrees of evangelical zeal. Promoted are a range of adjectival leaderships: “democratic” leadership, “strategic” leadership, “breakthrough” leadership, and so on.

Mulford (2008, p. 38).

There are many more adjectival models (for example “servant” leadership, “teacher” leadership, “collaborative” leadership, and “managerial” leadership), but for reasons of space these cannot all be included. The next part of this article will focus on those which most research reports have reported as being associated with successful student outcomes. In doing so, it will highlight their present strengths and limitations, finally pointing forward to the use of complexity theory perspectives as a means of transcending the “one size fits all” leadership “models”, “perspectives”, “pathways” and “frameworks”. It will also note that most of these are based on research in Western cultures, and point to the need for more research to take account of different cultural inheritances internationally.

Major models of school leadership: strengths and limitations

About seven major school leadership “adjectival” models have been developed since the Effective Schools movement. These include instructional, transformational, moral, participative, managerial, and contingent forms of school leadership (see more details about these models in Leithwood and Duke, 1999), as well as, more recently, distributed (Gronn, 2002; Leithwood and Jantzi, 2000; Spillane, 2017; Spillane et al., 2001) and inclusive or culturally responsive leadership (Ryan, 2006; Khalifa et al., 2016). These

last two may be more accurately represented as focusing upon social justice issues, and would be placed within the previous six. Among these, instructional and transformational models of leadership have been the most empirically studied, and have been advocated as promising approaches to understanding principals' contributions to improved student achievement and school reform.

Instructional leadership

Emerging from the research on "instructionally effective elementary schools" (e.g., Edmonds, 1979), this leadership model has undergone four decades of development and a variety of conceptualizations (see major developments in Andrews and Soder, 1987; Bossert et al., 1982; Hallinger and Heck, 1996; Hallinger and Murphy, 1985; Heck et al., 1990; Heck and Moriyama, 2010; Heck and Hallinger, 1999; Leithwood et al., 1990; Leithwood and Montgomery, 1982). To date, the model that has been clearly defined and reliably measured was developed by Hallinger and Murphy (Hallinger, 2005; Hallinger and Murphy, 1985; Murphy, 1990). Three dimensions with 10 leadership functions were conceptualized: *Defining the School's Mission, Managing the Instructional Program, and Promoting a Positive School Learning Climate*. Instructional leadership is claimed to influence the quality of school outcomes through the alignment of school structures and classrooms by means of the school's culture, and through modeling rather than through direct supervision or evaluation of teaching (Hallinger and Heck, 1996; Heck and Hallinger, 1999).

Whilst this "model" of school leadership is attractive and widely recognized amongst policy and practice communities, it is limited in its contribution to knowledge of what makes leadership successful. This is in part because it plays into the policy driven primary importance of functional outcomes, and in part because it assumes that better teaching will necessarily lead directly to better student outcomes in tests and examinations. In addition, even its advocates have found that, although emphasis on improving instruction is educationally meaningful, its direct impact is small.

Hallinger (2015), Robinson et al. (2008).

Transformational leadership

Transformational leadership (TSL) was introduced into the education field in the early 1990s to meet the demands of school restructuring (Hallinger, 1992; Leithwood, 1992; 1994; Podsakoff et al., 1990). Leithwood and his research colleagues developed transformational school leadership to its fullest form over a number of years (e.g., Leithwood and Jantzi, 1999, 2005; Leithwood and Steinbach, 1991; Leithwood et al., 1996; Leithwood and Sun, 2009). Their most recent version (Leithwood, 2017; Leithwood and Sun, 2012; Leithwood et al., 2004) expanded the concept of transformational school leadership to include five broad categories of practices with a total of thirteen specific sets of practice: *Setting Directions, Developing People, Redesigning the Organization, Improving the Instructional Program, and Managing and Securing Accountability*. The addition of leadership practices unique to a school setting that support instruction in schools, build an instructionally helpful school culture and collaborative structures, develop teachers, and engage communities is a major departure from the earlier models of transformational leadership developed in non-educational settings (e.g., Bass and Avolio, 1989), and from most other transformational school leadership models.

Transformational school leadership has been reported to be most effective in prompting positive individual perceptions of leaders, improving individual psychological states, achieving shared goals, nurturing cohesiveness and collaboration within schools, improving school culture and conditions, and having a small but significant impact on student learning (Leithwood and Sun, 2012; Sun, 2016; Sun and Leithwood, 2012). However, because the majority of findings on TSL impacts have been based on more narrowly conceptualized models, its actual impact on the many outcomes now required by schools, especially teaching and learning, is not clear yet.

Nevertheless, transformational leadership is a more inclusive model of leadership than Instructional. It subsumes Instructional leadership within its key strands of "Developing people" and "Improving the instructional programme", and goes beyond this, though it is important to note that this is disputed by adherents to Instructional leadership models.

Moral leadership

Implicit within transformational leadership is the importance attached to leadership values. Since the call from Greenfield (1976, 1978) for a value-laden inquiry into educational administration in the 1970s, a group of scholars has been developing research based on values theory (e.g., Hodgkinson, 1991; Sergiovanni, 1992; Starratt, 1994; Begley, 1996, 2003; Willower, 1997). Long ago, Hodgkinson (1991) argued, "Values constitute the essential problem of leadership—If there are no value conflicts then there is no need for leadership" (p. 11). Two central issues in moral leadership are "the nature of the values used by leaders in their decision-making, and how conflicts among values can be solved" (Leithwood et al., 1999, p. 10). In the last four decades, scholars have approached moral leadership in four ways: ethical reasoning; ethics as a way of informing perception and understanding; the purpose of education and the roles of educators; the establishment of caring schools; and naturalistic inquiry or valuation (Sun, 2011). The outcome of moral leadership is claimed to be morally justified decision-making, responsive, and democratic schools and classrooms (Leithwood and Duke, 1999; Noddings, 2013). Recently scholars have begun to develop measures of ethical leadership and its effects (e.g., Langlois et al., 2014).

It may be argued that moral leadership exists within the value systems of the successful application of both Instructional and Transformational leadership, rather than being a separate “model” in its own right.

Inclusive and culturally responsive leadership

Inclusive school leadership, arguably closely embedded in moral leadership values which include a belief in equity, was developed from the perspectives of critical theory and social justice. The first detailed inclusive leadership framework for schools was developed by Ryan (2006). According to him, inclusive leadership consists of a number of distinct practices, including advocating for inclusion, educating participants, developing critical consciousness, nurturing dialog, emphasizing student learning and classroom practice, adopting inclusive decision and policy-making strategies, and incorporating whole-school approaches. Expected outcomes of this kind of leadership include, increased awareness of injustice and inequity, increased emphasis on inclusive student learning, and enhanced instructional capacities and professional commitment (Ryan, 2006). A group of scholars (e.g., Gay, 2010; Johnson, 2006; Webb-Johnson and Carter, 2007) have extended this line of research by exploring *culturally responsive school leadership*, advocating culturally responsive classrooms and teaching, arguing that reforming and transforming all aspects of the educational enterprise, such as funding, policymaking and administration are needed, so that schools can be culturally responsive, especially with minority students. Culturally responsive leadership behaviors include: developing culturally responsive teachers; promoting a culturally responsive/inclusive school environment which engages students, parents, and indigenous contexts (Khalifa et al., 2016).

So far, inquiry into inclusive or culturally responsive school leadership is still at the conceptual stage. More empirical evidence is needed to understand its presence in successful leaders, and its influence on student or other school outcomes.

Distributed leadership

Although not a model in its own right, but rather, as with moral, and inclusive and culturally responsive, expressive of values held by successful transformational or instructional leaders, a distributed perspective of school leadership has been introduced and developed over the last two decades (Leithwood et al., 2009; Spillane et al., 2001, 2004; Spillane, 2017). Building upon work from other disciplines (e.g., Gronn, 2002), scholars have defined the concept of distributed leadership in different ways. Leithwood and his associates (Leithwood et al., 2009), for example, conceptualized distributed leadership as being exhibited in four forms based on leadership coordination: planful alignment, spontaneous alignment, spontaneous misalignment, and anarchic misalignment. Planful alignment is claimed to be more effective than the other three forms of leadership distribution, for example, in developing a safe and inclusive school environment (Anderson et al., 2009), and improving student learning (Leithwood et al., 2010). Day and his colleagues in a national mixed methods study found that planful distribution of leadership was progressive, associated with the building of trust by principals, took time, and is one of a number of factors which contribute, indirectly but powerfully to improvements in students’ attainment (Day et al., 2011).

Premised on activity and distributed cognition theories, Spillane and his associates (Spillane et al., 2001, 2004), were among the first scholars to apply distributed perspective as a frame for studying leadership practice. They focused on the productive and collegial interaction of all stakeholders, and argued that the conceptualization of the distributed leadership is not just about the actions of individual leaders, but rather, about *interactions* among leaders followers, and the situation. Further, he (Spillane, 2017) conceptualized instruction as being collective, situated, and distributed practice, not equivalent to a teacher’s behavior or a function of her/his knowledge and skill, but rather seen in the form of interactions between teachers and students related to particular intellectual material and to aspects of the situation. The role of teachers in leadership, and formal leadership roles in the spaces between school-wide senior leaders and classroom teaching colleagues have also been examined more in depth, as reflected from by two lines of research: teacher leadership (e.g., Muijs and Harris, 2003), and more recently, middle leadership (Day and Grice, 2019).

“Distributed” leadership focuses upon an important part of leadership which is likely to lead to success and thus is more finely delineated than the broader term of “effective”. Moreover, as with “moral” and “culturally responsive” leadership, distributed leadership is not a model but a value and a strategy; and would fit within the successful application of the “transformational” leadership model. As currently conceptualized, it does not take into account the influence of different educational histories or cultures, for example the prevailing “power-distance” culture in many Asian societies. Nevertheless, it does highlight the importance of recognizing that successful principals and the schools which they lead do not readily “fit” within any given model of successful leadership.

Five leadership frameworks

Several integrated, overarching school leadership frameworks have been developed in this century based on systematic reviews. We highlight five of these:

1. An extended version of Leithwood’s earlier work is the Ontario Leadership Framework (OLF) (Leithwood, 2012, 2017). Hitt and Tucker (2016) claimed that this is the most comprehensive school leadership framework to date. It not only includes *practices*

conceptualized in different leadership models such as transformational, instructional, and using distributed leadership practices, but also *personal resources* (cognitive, social, and psychological resources, along with values and ethics), and the *interaction* of leadership behaviors with contextual factors (i.e., information about how, where and when to enact those practices), the most important elements identified from different approaches to leadership in the past three decades. In this sense, it is the most holistic framework for capturing the complexities of successful school leadership to date.

2. Hitt and Tucker (2016) identified and compared three existing, noteworthy leadership frameworks: the OLF, the Learning-Centered Leadership Framework by Murphy et al. (2006), and the Essential Supports Framework derived by Sebring et al. (2006). They identified and classified 28 practices from these frameworks into five domains, and proposed a “United” Framework. These five domains are: establishing and conveying the vision; facilitating a high-quality learning experience for students; building professional capacity; creating a supportive organization for learning; and connecting with external partners.
3. A third major leadership framework is “Balanced” Leadership, consisting of 21 leadership responsibilities practices significantly correlated with student achievement identified by Waters and his colleagues (Waters et al., 2003) through a meta-analysis. It includes 21 leadership responsibilities, some of which are effective for first-order (direct) changes and the others are effective for second-order (indirect) change.
4. Robinson and her associates in New Zealand (Robinson et al., 2008) identified and proposed a school leadership framework based on a “best evidence synthesis” of selected quantitative studies on effective school leadership internationally. This framework consists of five domains of leadership practices found to influence student achievement effectively: establishing goals and expectations; resourcing strategically; planning, coordinating, and evaluating teaching and the curriculum; promoting and participating in teacher learning and development; and ensuring an orderly and supportive environment.

Leithwood and his colleagues (Leithwood et al., 2010, 2020) identified most promising empirically tested mediating school conditions from research evidence drawn from schools in Ontario, Canada. These were classified into four categories, and populated on Four Paths: Rational, Emotions, Organizational, and Family. School leaders, they claim, influence student learning through these four paths. Variables on the Rational Path are rooted in teachers’ knowledge and skills related to curriculum, teaching, and learning—the technical core of schooling. The Emotional Path includes teachers’ feelings, dispositions, or affective states, both individually and collectively. Variables on the Organizational Path include features of schools that structure the relationships and interactions among school members including, for example, cultures, policies, and standard operating procedures. Variables on the Family Path include those that reflect family expectations for their children, their culture and their support for their children, and community orientations toward school and general education. The variables on each of the four paths are potentially alterable by school leadership.

Leadership influence and impact

While these and hundreds of other, smaller scale studies, each applying a specific model of leadership, or interpreted framework that, have reported the influence of school leadership on a variety of school outcomes, the impact of school leadership on student learning has remained the most difficult to examine conceptually and methodologically due to its indirect nature. Research on school improvement and leadership over the last 30 years has identified significant school-level contributors to student learning, such as academic press and teacher collective efficacy (e.g., DiPaola and Hoy, 2005; Hoy and Miskel, 2013), and a small number of combinations of such variables (e.g., Bryk et al., 2010; Heck and Hallinger, 2014; Mitchell et al., 2016; Sebastian et al., 2017). These variables can be shaped significantly by school leadership. Very limited quantitative evidence shows important indirect impacts of school leadership (mostly transformational, and/or instructional models, or OLF) on student achievement through such mediating variables, moderated, or not. (e.g., Leithwood et al., 2010, 2017). As reported in the largest, five year mixed methods educational leadership project, funded by the Wallace Foundation, based on data from thousands of teachers in 180 schools in eight states in the USA, schools leaders have an impact on student achievement primarily through their influence on teachers’ motivation and working conditions. However, the study found that their influence on teachers’ knowledge and skills produced less direct impact on student achievement. Rather, it was collective leadership, particularly from teacher teams, parents, and students that, was claimed to have a stronger influence on student achievement than individual leadership (Leithwood and Louis, 2012).

While each of these models, perspectives and frameworks contributes to understandings of the qualities, values and capabilities (knowledge, skills) that leaders need, none of them alone capture how leaders assure student success over time.

Only a few studies have used both qualitative and quantitative longitudinal data to examine the link between school leadership, teacher and teaching effectiveness, and change in student learning (Day et al., 2011; Mulford and Silins, 2003). These two large scale, mixed methods researches, in Australia and England, and extensive case study research carried out by members of the International Successful School Principalship Project (ISSPP) over a twenty year period, have succeeded in providing substantive evidence of the “how” and “when”, of successful principalship, as well as the influence of cultures and contexts.

IMPACT project (England)

Based on student outcome data over at least a three year consecutive period showing improvement under the leadership of the same principal, national survey data including responses from 740 heads and 1775 key staff, and multi-perspective in-depth case studies of a subsample of 20 schools, Day and his associates (Day et al., 2016) investigated associations between principalship in effective and improving 1549 primary and 1140 secondary schools in England and student outcomes as defined (but not confined) by their national examination and assessment results over 3 years. This is most representative and comprehensive study using mixed methods and national longitudinal data in a single study. They found that successful principals directly and indirectly achieve and sustain improvement over time through values-led leadership which combines both transformational and instructional leadership strategies in ways which demonstrate consistency of values, possession and enactment of particular qualities, and strategies. Their research demonstrates that schools' abilities to improve and sustain effectiveness over the long term are not primarily the result of the principals' leadership "style" or "personality traits," but of their understanding, discernment and diagnosis of the school's needs and their application of clearly articulated, organizationally shared educational values. The research found that: (i) certain core leadership practices are effective in improving student learning across countries and across settings; (ii) successful principals are all values -led, possessing similar core attributes and qualities; (iii) they "layer" and enact multiple combinations and accumulations of key practices are strategically applied in different contexts for different periods of time, and progressively embedded in the school's work, culture, and achievements; (iv) the ways in which leaders apply leadership practices demonstrate responsiveness to, rather than dictation by, the contexts in which they work; and (v) they distribute leadership progressively according to levels of trust.

Australia

The Leadership for Organizational Learning and Student Outcomes (LOLSO) Research Project (Mulford and Silins, 2003) extended the understandings of school reform initiatives that aim to change school practices with the intention of supporting enhanced student learning (defined more broadly than academic achievement). A four year, longitudinal project, involving 3500 students and 2500 of their teachers and head teachers in 96 Australia secondary schools, it demonstrated that leadership that makes a difference to a high school has a community focus, sense of being valued among staff, and organizational leadership, and is transformational and distributive. It was one of the earliest research large scale projects outside of the USA and England that confirmed that school leadership influences students indirectly, by contributing to organizational learning, which in turn influences what happens in the core business of the school—the quality of teaching and learning.

The international successful school principalship project: embracing complexity, acknowledging culture

There are numerous global educational leadership projects that have focused on effective leadership. Of these, the ISSPP is the largest and longest running, spanning twenty countries over twenty years. Conducting multiple perspective, multi-level case studies using common research protocols, members of the ISSPP network have collectively produced the largest international, authoritative corpus of more than 150 case studies and more than 200 journal papers, book articles and books (Gurr and Moyi, forthcoming). It has been suggested that the ISSPP "is the most comprehensive and coherent international comparative study of the principalship ever undertaken." (Caldwell, 2014, xxii).

Determining what is success, who is successful, and how success is achieved is important in school leadership research. Success is a value, a process, an outcome, and an end in view, which is ongoing, as successful schools and their leaders do not stand still. Nor does success necessarily suggest a shared or transferable solution. In this on-going multi-national project, researchers across all participating countries have found that success does not have the same meaning as "effectiveness", or "improvement". *Successful principals, they found, are defined broadly across all jurisdictions and countries, cultures, and socio-economic contexts as those who attend, with their teachers, to moral, social, and ethical issues when educating students, as well as to their students' measurable achievements.*

Its members' work explores the qualities, characteristics, practices and identities of school principals who are successful over time in different countries and cultural settings. Its research focuses on how success is built and sustained over time in schools in rural and urban settings, and challenging socio-economic contexts; principal identities; and "visible" and "invisible" low performing schools, as well as educational career and principal preparation programs (Crow and Whiteman, 2016), and middle leadership (Farchi and Tubin, 2019; Gurr et al., 2018).

The studies in the member countries of the ISSPP project consistently indicate: (i) the importance of considering the part played by the combination of personal, professional, situational, policy and broader cultural contexts in achieving and sustaining success; (ii) the degree to which principals are respected and trusted by their school colleagues and external school communities; and (iii) the ways that relational trust, capacity, capability, shared professional practice, and individual and collective agency and efficacy, and raised levels of teaching, learning and student achievement are built successfully over time. These inform principals' diagnoses of need and their timely, contextually sensitive, consensual decision-making. Always in the ISSPP research findings, responding to "context" is defined as being the making of decisions which are taken in the broader as well as narrower interests of all interested stakeholders.

ISSPP research notes that transformational, instructional, distributed leadership all support successful principalship, depending on the degree of coordination and independence fostered, and the enabling of deep levels of trust and trustworthiness through

collaborative dialog; and that *values-led integrated leadership best represents the work of principals in successful schools as they tackle new contingencies within the complexity of their contexts*. How they express their values through management leadership systems and culture are key to their leadership success (Day, 2017).

Finally, the research in this project has found that school success is not achieved by the action—or inaction—of a single (heroic) person, but by the collective will and work of these and other leaders and teachers, and achieved through both the direct and indirect influence of principals.

The ISSPP studies have confirmed many of the earlier research studies and been able also to provide new insights and powerful images, particularly about the kinds of reflexivity, inner values, philosophies, and intra-as well as inter-professional qualities, skills, and strategies that successful principalship demands, regardless of culture, country, and school context; and they provide empirical affirmation of what was proposed by scholars 20 years ago (Hallinger, 1995; Hallinger and Heck, 1998; Hallinger and Leithwood, 1998; Heck, 1996; 1998; Leithwood and Duke, 1999; Walker and Dimmock, 2002), that certain parts of school leadership could be universal, i.e., culture-free; and other parts could be culture-specific (Day et al., 2020).

All three of the above studies have revealed more nuanced understandings of successful principals' work and lives in school contexts of complexity and change than those gained from research on particular "models," "frameworks" or "pathways" of leadership, or from "effective schools" and "school improvement" research discussed earlier in this article. However, the work of ISSPP members most closely embodies two key developments in the progressive nuancing of conception and conduct of school leadership research—the importance of acknowledging complexity, and of embracing cultural differences. This is in large measure because, either implicitly or explicitly, their research acknowledges that schools are complex adaptive systems, nested within and interactive with a number of other interconnected systems.

Complexity theory

What is unusual in school leadership research is that the ISSPP research is explicitly embedded in understandings that schools are complex adaptive systems, and that in these contexts, "rather than leading for efficiency and control, appropriate to manufacturing ... [successful]...organizations find themselves leading for adaptability, knowledge and learning" (Uhl-Bien et al., 2007, p. 301). In this conception, leadership has three main functions: adaptive (creative, that emerges from interactions); administrative (the formal leadership role); and enabling (combinations of bureaucratic (administrative) and emergent (adaptive)). Essentially, this notion arises from an understanding of schools as "living systems" in which:

There is no objective reality out there waiting to reveal its secrets. There are no recipes or formulae, no checklists or advice that describes "reality." There is only what we create through our engagement with others and events. Nothing really transfers; everything is always new and different and unique to each of us.

Wheatley (1992, p. 7).

The ISSPP research assumes that leaders are part of a profession, part of a school organization that is also part of the whole educational system, that is itself part of a country's cultural heritage. The system affects the environment and the environment affects the system (Morrison, 2002). Bronfenbrenner's (1995) "ecological systems theory" complements this, presenting a number of interactive system layers, each nested in and interactive with the others: micro (immediate environment of the classroom), meso (connections in the school), exo (indirect environment), macro (social/cultural values), and chrono (changes over time). The underlying rationale for the use of ecological systems theory, as found in much of the ISSPP research about successful leadership, is: (i) a view that schools are dynamic, policy influenced but not directed, task driven and relational in their nature; (ii) that success goes beyond the "functional", and (iii) that successful principals are agential, rather than compliant, influential through how they think and feel, who they are, what they do, and how they do it. The ISSPP research has found that successful principals *understand* that human behavior is likely to be complex, non-linear, interdependent, emergent, and uneven at and between different levels of this system, and that they are able to adapt to their ever-changing environments with values-based "systems thinking" (Day and Gurr, 2014; Day and Leithwood, 2007; Day and Gu, 2009 Day et al., 2011; Jacobson et al., 2005; Ylimaki and Jacobson, 2013).

Complexity theory in educational research suggests multiple causalities and multi-directional causes and effects (Cohen et al., 2011). This requires a paradigm shift for many, toward a "holistic, connectionist and integrationist view of the individual and the environment, rather than a fragmented, reductionist perspective" (Youngblood, 1997, p. 34). To date, there is relatively little research on system change which focuses, as the ISSPP research does, on the behaviors of individual agents and the relationships between these within a multi-level ecosystem (Jacobson et al., 2019, p. 113). In effect, these studies synthesize the new contextually-oriented, culturally informed, complexity-based knowledge about the nature of schools and successful school leadership, reaching beyond the previous successful school leadership research findings.

Cultural Differences

Educational leadership researchers cannot assume that all schooling is materially or functionally similar. Schooling and school resourcing do not operate in the same way in different countries, states and jurisdictions, or even within cities and sectors themselves. Within and between each of these are cultural assumptions about the purposes of schooling, what success means, and

who defines it. These assumptions may be unique to a school context, may be driven by national government education policies, and are increasingly determined by shared global assumptions about success, including the UNESCO sustainable development goals where education is fourth in priority, OECD research, and PISA test scores. Therefore, what determines success may be specific to a context, may travel between contexts, or be shared or borrowed by different contexts.

Country specific inherited cultures play an important part in principals' values, professional identities, the way they form relationships, and the way they lead. Culture can be defined as "the interactive aggregate of common characteristics that influence a human group's response to its environment" (Hofstede, 1980, p. 10). These visible manifestations of culture include values, symbols, heroes, and rituals. Culture shapes, but does not necessarily determine, the institutional and community context within which the school is situated, influences the predilections of individual leaders and the nature of their interactions with others in the school and its community, and strongly influences the particular educational emphasis or goals that prevail within a system of schooling (Hallinger and Leithwood, 1996). Culture can relate to the group of people at the school level (organizational culture) or at the national/regional level (societal culture) (Walker and Dimmock, 2002). Culture-common concepts can be found among people from different societies and cultures; culture-specific concepts represent different ways that people deal with culture-general demands, "both of which are necessary for an understanding of culture and cultural differences" (p. 71). Given the current convergence in understanding and development of school leadership globally, the study of school leadership across cultures can unveil distinctive features of leadership that are particularly effective in specific nations or cultures, and which should be celebrated (Walker and Dimmock, 2002).

The research of ISSPP found that, while the social, political, cultural, and educational histories of schools differ from country to country, all principals experienced change driven by the ever-increasing interest of central and municipal governments in measurable "performance" and "performativity", attended to new trends in instruction (e.g., personalization of the learning experience; teachers working collaboratively; greater use of feedback to improve performance at student, teacher, parent, school, and system levels), had a strong sense of moral and social/ethical purpose, shared the same cluster of values (e.g., caring for students, a love of learning, high expectations), increased their use of technology to support learning and qualities, strategies, actions, and relational connectedness, and enacted a set of core leadership practices (Day and Gu, 2009). According to this research, successful school principals focus on creating, establishing, sustaining, revisiting and where necessary renewing a set of curriculum, teaching, learning, achievement and relational principles and practices which are ethically, functionally and socially defensible, and relevant to the learning and achievement needs of every student in their school. They do this by understanding, acknowledging, and respecting the norms of external policy directives and the national and local cultures in which the school is located. They are not, however, always compliant with these, where they judge them not to be in the students' best interests. It will be evident from this, that successful leaders regard themselves as change leaders with strong ethical and moral purposes. Rather than acting as unquestioning implementors of externally defined policies, successful leaders interpret, modify, and incorporate these into preferred, values-led cultures and practices. In order to be successful, they know, also, that their priority must always be the quality of their students' learning, achievement and wellbeing, that they cannot achieve this directly or by their efforts alone, but that they can influence this indirectly through working in different ways over time to influence staff, students and their parents to work together for the longer-term broad as well as narrow educational benefits of the students. It is in choosing the right ways at the right times and with the right sets of internal and external relationships that they achieve success.

Such accumulations of multi-level case studies and longitudinal mixed-methods research designs as those above have the advantage of providing finer grained, more nuanced evidence-based understandings of the leadership roles and behaviors of principals who achieve and sustain educational outcomes in schools than single lens quantitative analyses, meta-analyses, or purely qualitative approaches. The findings provide support for more differentiated, context sensitive training and development for aspiring and serving principals. The importance of contextual influences identified by the Australian, English and ISSPP research were later affirmed by Hallinger's research, aptly entitled, "Bringing Context out of the Shadows" (Hallinger, 2016).

Future directions

As we move further into the 21st century, our educational contexts are likely to continue to be characterized by features such as accountability, globalization, and diversity. Research on successful school leadership needs to continue to be open to finding new elements to enhance its effectiveness and strength in new contexts. With the emergence of more empirical research and parallel evidence, comparative studies across continents can shed light on advanced leadership theories on an international platform. Findings about successful leadership exhibit certain commonalities across very different settings. The examination of successful leadership practices that are both culture-free and that are culture-specific can best inform leadership development within different contexts in a global context.

The research cited in this article unambiguously demonstrates the schools in this century are not static entities; they are complex adaptive systems, coping with uncertainties and complexity related to teachers, students, dynamic network structures, workload, school size, school level, policies, cultures, regions and countries. It follows that successful school leaders are adaptive, recognizing that classrooms at the micro level are nested within and interact with schools (at the meso level); that schools themselves are nested within and interact with policy, part of the indirect environment (the exo level), and society (at the macro level); and that all are subject to changes over time (the chrono level). It demonstrates, also, however, that working within and across these, principals who

succeed carry with them their resolute commitment to broad humanitarian educational values, equity *and* academic progress and achievement.

Thus, while the development of models, frameworks and pathways provides insights, these are unduly limiting. A further development of research within and across national jurisdictions using a combination of Integrated frameworks, or “pathways” and based on a view of schools as complex adaptive systems, would signal: (i) a growing awareness of the need to differentiate “effective” from “successful principalship”, the former being largely concerned with the functional, and the latter being concerned with both the functional and affective; (ii) a growing understanding of schools as complex systems which are nested in macro, exo and chrono systems and cultures, and which are influenced but not necessarily dictated by the vagaries of changing external policies and changes in societal demands; and (iii) an enhanced awareness of the importance of external, culturally inherited conceptions and practices of successful leadership. Identifying more indigenous elements of school leadership and its unique influence pathways, and more indigenous instruments developed in different cultural contexts, could help to develop indigenous leadership theories, which, combined with Western leadership theories, would eventually help us to understand and develop leadership with a global view and application.

Research now needs to examine more closely how leaders influence teachers and especially the quality of teachers’ work in classrooms in more detail, combining and complementing statistical structural equation modeling with qualitative methods in order to discover *how* change happens in classrooms as a consequence of principals’ influence and interventions.

While multi-level cultural perspectives need to be adopted to aid understanding of schools and their leaders, recent statistical advances (such as structural equation modeling and hierarchical linear modeling) also hold the promise of allowing researchers to investigate models across groups (e.g., schools or cultural settings) or between organizational levels (e.g., classes within schools within districts) or cultural layers (e.g., schools within communities within cultural settings). Research methods that incorporate the intuitive insights and speculative reflections of the observer from qualitative data and then submit them to systematic empirical testing offer the best hope for fulfilling the full potential of a comparative study. These will help to inform a more integrated, cross-cultural, sophisticated leadership theory that can meet the demands of globalization in the 21st century.

Two decades ago, Walker and Dimmock (2002) suggested that a cross-cultural comparative approach would allow administrative and leadership practices in different societies and cultures to be seen in relation to each other. As long as the bulk of theory and practice in the field is drawn almost exclusively from culturally conceived Anglo-American beliefs, philosophies, and understandings, our understandings regarding the field of educational administration and leadership are likely to remain partial and incomplete.

Introduction

This paper unpacks the meaning of integrated educational leadership (IEL), as it has typically been used in the educational leadership literature. Evidence is also summarized about the effects of such leadership on both school organizations and students. Throughout the paper, the work of my colleagues and me,^a especially as it has become embedded and extended in the *Ontario Leadership Framework* (OLF), is used to illustrate some features of IEL. A relatively comprehensive example of IEL, the OLF is also used to illustrate possible features of a major addition to most conceptions of IEL - leadership traits, dispositions or “personal leadership resources”.

Much of the research on leadership is focused on specific “models”. Typically, these are theoretical accounts of a selected set of leadership practices believed to be especially successful in accomplishing one or more valued organizational processes and/or outcomes. For example, *charismatic leadership* is about how to inspire followers to adapt and strive toward accomplishing a leader’s vision (Conger, 2015); *ethical leadership* stresses the importance of basing decisions on such widely held values as fairness, equity, transparency, honesty and the like (Brown and Trevino, 2006); *leader-member exchange theory* is about the importance of different types of relationships between leaders and followers (Gerstner and Day, 1987); and *servant leadership* encourages leaders to appreciate, and then fulfill, the needs and aspirations of followers (Greenleaf, 1996); *inclusive leadership* acknowledges the priority now awarded to leaders’ efforts at ensuring the educational needs all of their students are met (Khalifa et al., 2016a,b); and *distributed leadership* emphasizes making productive use of leadership resources potentially located in many people across the organization (Harris, 2013). Leadership models such as these typically excel in the coherence of their formulations and some have been the object of extensive empirical testing. Their attraction is due, in no small part, to the simplification of an otherwise highly complex role or function which demands a wide array of different practices, all contingent on the context in which leaders find themselves. Those practices are, themselves, shaped by a host of personal traits or dispositions. Such simplification is achieved by the focus of most leadership models on one or several undeniably important parts of what effective leaders actually do while ignoring the rest.

^aThis is work reflected in a four-decade long research program with colleagues and students. About a decade ago, this work was given considerable additional impetus through the formation of a partnership with the Canadian province of Ontario’s Ministry of Education and Ontario’s Institute for Educational Leadership. This partnership resulted in the *Ontario Leadership Framework* (Leithwood, 2012, 2020), now widely used in the province as a guide to leadership selection and development. As this paper is being written, the Framework is in the final stages of being updated and revised.

Adopting the position of test theorists, one might argue that those undeniably important parts of leadership can be treated as representative samples of the leadership domain as a whole. Leaders who enact those undeniably important parts of what effective leaders do, according to this position, can be expected to enact most of the other important parts, as well. There is no evidence to either confirm or disconfirm this argument. Alternatively, however, one might plausibly argue that the positive evidence about leadership effects, based on the conceptions of leadership represented by most leadership models, must radically underestimate those effects since such a small proportion of leaders' actual work is taken into account. Both of these positions, however, would encourage conceptions and measures of leaders' work that more fully capture what leaders actually do whenever feasible. This has been the basic warrant giving rise to the development of IEL models.

Integrated educational leadership

The concept of IEL became especially visible in 2003 with the publication of two papers. Hallinger (2003), reviewed relevant concepts and evidence, identified practices the literature had associated with both instructional leadership (IL) and transformational leadership (TL) to that point, and identified the similarities and differences between practices associated with the two approaches. Marks and Printy (2003) tested the relative effects of a selected sub-sample of IL and TL practices on classroom instruction and student achievement. A combination of the two sets of practices, they found, had significantly larger effects than either set of practices separately. Most subsequent research on IEL has assumed that it is the combination of practices associated with these two leadership models (Robinson et al., 2008).

While Hallinger (2003) and Marks and Printy (2003) provided much of the impetus for subsequent research on IEL, Dwyer (1985)^b anticipated important features of that work in his earlier study of IL. The results of that study identified what Dwyer referred to as two forms of principals' IL. One form was represented by a group of successful school leaders who focused primarily on setting the conditions of instruction in their classrooms ("working with their staffs to define and coordinate the what, when, where, and how of instruction" p. 14); this focus conforms closely to early views of IL that emerged from the effective schools movement. A second group of successful school leaders in Dwyer's study focused largely on setting the conditions for instruction in their schools "providing school environments that are supportive of teachers' work and students' learning" (p. 14); this focus reflects much of how TL is enacted in school contexts. So, Dwyer's (1985) study can be viewed as anticipating the IL/TL concept of integrated leadership as one which entails leaders setting the conditions both of and for instruction.

Instructional leadership (IL)

With a long history rooted in the effective schools movement (e.g., Edmonds, 1979), clear and testable models of IL have been proposed, for example, by Hallinger and Murphy (1985), Blasé and Blasé (2000) and others. Encompassing recent concepts such as "leadership for learning" (Hallinger, 2009; Knapp et al., 2012), the idea of IL still dominates the aspirations of a great many practicing school leaders even though the exact meaning of IL varies across models. Although sometimes accused of being too principal-centric and top down, shared or distributed conceptions of IL were advanced very early in research about IL (e.g., Dwyer, 1985; Rosenholtz, 1985). This shared conception of IL continues to receive considerable support (e.g., Bush, 2015; Supovitz et al., 2010).

While most models of instructional leadership place considerable weight on the relatively direct engagement of leaders in their school's instructional programs, the nature of that engagement varies. Three explicit models of IL illustrate such variation, as well as their "family resemblance". The most explicit, detailed and fully tested model of IL was developed by Hallinger and Murphy (Hallinger, 2005; Hallinger and Murphy, 1985; Murphy, 1990). This model includes three categories of practices - *Defines the school mission*, *Manages the instructional program* and *Develops a positive school learning climate*. A total of eleven sub-categories are included in this model. *Defining the school mission*, for example, encompasses the sub-dimensions *framing the school goals* and *communicating the school goals*.

A second example of an IL model, by Blasé and Blasé (2000), includes just two major dimensions of effective principal behavior. The first dimension, *Talking with teachers to promote reflection* includes *giving feedback*, *modeling*, *soliciting advice and opinions* and *giving praise*. The second dimension, *Making suggestions*, encompass nine behaviors, for example, *listening*, *sharing experience*, *giving teachers choice*, *encouraging risk taking*, and *recognizing teachers' strengths*. Bryk et al. (2010) is a third example. This IL model conceives of multiple principal leadership roles *developing the mission and goals of the school*, *setting high standards and communicating expectations to staff*, *developing trust and collaboration among staff*, and *supporting instruction*.

Based on a "broad reading of the literature on instructional leadership" since Dwyer's (1985) study, Hallinger (2005) indicates that conceptions of IL typically focus on some or all of the following dimensions:

- "Creating a shared sense of purpose in the school, including clear goals focused on student learning;
- Fostering the continuous improvement of the school through cyclical school development planning that involves a wide range of stakeholders;

^bAlthough now 35 years old, this remains one of the most methodologically impressive IL studies ever conducted. A considerable proportion of what subsequent studies of IL report do very little to advance Dwyer's findings even though leaders' contexts have changed dramatically.

- Developing a climate of high expectations and a school culture aimed at innovation and improvement of teaching and learning;
- Coordinating the curriculum and monitoring student learning outcomes;
- Shaping the reward structure of the school to reflect the school's mission;
- Organizing and monitoring a wide range of activities aimed at the continuous development of staff; and
- Being a visible presence in the school, modeling the desired values of the school's culture" (p. 233).

Transformational leadership (TL)

Accounts and evidence about transformational leadership, initially emerging from research in non-educational organizations, attracted significant attention by educators beginning in the late 1990s. In his seminal publication, Burns argued that transforming leadership "occurs when one or more persons *engage* with others in such a way that leaders and followers raise one another to higher levels of motivation and morality (1978, p. 20). Leaders do this by developing a vision for the organization, developing commitments and trust among workers, and facilitating organizational learning. Unlike many earlier theories of leadership which emphasized rational processes, transformational leadership theory emphasizes emotions and values, attributes of importance to symbolic behavior, and conceptualizes the role of the leader as helping make events meaningful for followers (Siangchokyo et al., 2020).

While closely aligned versions of transformational leadership were proposed by Burns (1978), Bass (1985) and Podsakoff et al. (1990), Bass launched an extensive program of empirical research (e.g. Bass and Avolio, 1994) which provided, among other things, evidence to justify the value of four categories of transformational leadership practices. These categories include *idealized influence*, *inspirational motivation*, *intellectual stimulation*, and *individualized consideration* (along with three transactional dimensions). To these dimensions, Podsakoff et al. (1990) added *articulating a vision*, *providing an appropriate model*, *fostering the acceptance of group goals*, and *high-performance expectations*.

Illustrating the integration of IL and TL practices

Leithwood and his colleagues initially developed a set of transformational leadership practices by adapting and extending those identified most directly by Podsakoff et al. (1990) with the aim of better capturing the consequences for leaders of working in school organizations (e.g., Leithwood et al., 1999; Leithwood and Jantzi, 2005). There were three broad categories of such practices in this early formulation including *setting directions*, *developing people*, and *redesigning the organization*.

Leadership practices aimed at *redesigning the organization* are unique to this conception of transformational leadership, although some accounts of Bass's conception refer to the importance of leaders influencing organizational cultures and structures (e.g., Avolio, 1994). This third domain of practices responds to the limited explicit attention devoted to leaders' organizational contexts by most models of transformational leadership. As part of developing the OLF, a fourth dimension was also added (*securing accountability*), expanding the models' attention to a broad policy context which holds most school leaders accountable for advancing their schools' achievement of widely valued student outcomes.

Finally, this model includes a fifth domain (*Improving the Instructional Program*) encompassing practices that are part of most (direct) IL models (e.g., Hallinger, 2005). This domain reflects the well documented claim that a considerable proportion of leaders' attention should be devoted to the technical core of schooling (e.g., Robinson et al., 2008).

A total of 21 specific practices are included in the five domains of this integrated model, as they appear in the OLF, including:

- Summaries of evidence justifying each of the domains and practices
- Explanations of when and how each of the practices might be enacted
- Explanations of the causal relationship between the domains of leader practices, follower responses and such distal outcomes as student learning.

Integrated educational leadership effects

There is a strong conceptual argument, touched on above, favoring an integrated model of school leadership over either IL or TL models alone. Integrated models potentially capture a larger proportion of what practicing leaders do and, as a result, ought to explain more of the variation in leadership effects than does either IL or TL alone. This section summarizes the results of nine quantitative studies testing IEL effects. Although small in number, these studies likely capture the bulk of such research to date.

Marks and Printy's (2003) mixed methods study tested integrated leadership effects, as well as the separate contribution of IL and TL practices to those effects. Their measure of instructional leadership were questions asking teachers to rate the priority which leaders attached to instruction, teachers' sharing in such leadership outside their own classrooms and the mutual engagement of principal and teacher leaders in efforts to improve instruction. The measures of transformation leadership in this study was based on a sub-set of the transformational practices included in Leithwood's early work on TL (Leithwood et al., 1999; Leithwood and Riehl, 2005). Results indicated that the quality of instruction and the achievement of students in schools led by principals enacting high levels of integrated leadership were significantly better than in schools led by principals enacting low or non-integrated approaches.

Day et al. (2016) study was part of a much larger three-year, mixed-methods research program about the role of primary and secondary school leadership in improving and effective schools in England. This study used an integrated model of leadership (after Leithwood et al., 2008) to examine how the practices of leaders changed over time as their schools' organizational features, student performance and staffs' capacities changed. The authors sum up one important set of findings as follows:

...Neither instructional leadership strategies nor transformational leadership strategies alone were sufficient to promote improvement.... Leadership strategies that built on change in organizational structures and conditions but that focused more closely on developing people to become innovative and more rigorous in their teaching practices and to learn to use data and observation to improve their teaching also played an important role in school improvement processes (p. 253).

Two parallel studies conducted in Chicago high and elementary schools (Sebastian and Allensworth, 2012; Sebastian et al., 2017), tested the extent to which an integrated model of school leadership influenced the quality of classroom instruction and student achievement. While the authors refer to the leadership model they tested as "instructional" (direct and indirect IL), it conforms closely (if incompletely) to the conception of integrated leadership common to some other studies reviewed here. Direct IL was measured with a set of questions about teachers' perceptions of their principal as an instructional leader, as well as the extent to which their principal set high standards for teaching and learning, set school vision and goals and supported effective classroom instruction. Transformational leadership (or indirect IL) was reflected in items measuring the extent to which teachers felt that their principals had confidence in them, had trusting relationships with them, encouraged collaboration, and looked out for their personal welfare.

Results indicated that leadership on the part of both elementary and high school principals had significant associations with classroom instruction and student achievement. These effects were mediated through the schools' learning climate alone, a climate strongly influenced by teacher leadership, and measured by student perceptions of "whether they got along, treated each other with respect, cared about each other ... and the extent to which students felt safe inside and around the school buildings" (Sebastian et al., 2016, p. 83).

ten Bruggencate et al. (2012) tested the effects of an integrated conception of leadership on student achievement and promotion rates using evidence from principals (103), teachers (998) and students (4336) in 97 Dutch schools serving students in five grades starting at age 12. Mediating variables in this study included student engagement and several features of teachers' work (support for students, class atmosphere, organization of instruction), along with the tendency for school cultures to reflect a performance orientation or a development orientation. School leadership was conceptualized according to the *Conflicting Values Framework* (CVR) (Quinn and Rohrbaugh, 1983), a framework broadly representing four different value positions underlying research on organizational effectiveness, each at least loosely reflecting one of the OLF leadership domains— a rational position (*setting directions*) a human relations position (*developing people*), an open systems position (*redesigning the organization*) and an internal processes position (*improving the instructional programs*). While these parallels seem conceptually imperfect, some of the actual items used to measure leadership were similar to those in Leithwood's survey (2017).

Results indicated that leader behavior, in aggregate, had significant total effects on both the performance orientation and development orientation of school cultures. Leader behavior associated with rational goals and open systems values had positive total effects on teachers' work. Smaller effects of leader behaviors were associated with internal process and human relations values. Leadership reflecting values associated with CVR's rational goals and open systems had negative effects on student promotion rates.

Three studies have tested the effects of leadership practices included in the OLF and all three studies used the same measure of leadership. Boberg and Bourgeois (2016), examined the direct and indirect effects of this model of IEL on student math and language achievement. Collective teacher efficacy (CTE), organizational citizenship behavior (teacher extra commitment and effort) and student engagement were hypothesized to mediate the effects of leadership on student achievement. Evidence for this study was provided by teachers (569) and students in 63 public charter middle and upper schools located in the south-central regions/areas of the United States. Results indicated that IEL had significant direct effects on teacher commitment and effort, as well as CTE, and that CTE had significant direct effects on both reading and math achievement as well as on students' emotional engagement. The authors concluded that:

This study's [IEL] model demonstrates combined indirect effect sizes on reading and mathematics that reveal considerable improvements over all earlier TL models evaluated by Marks and Printy (2003), Robinson et al. (2008), and Scheerens (2012) (p. 368).

Leithwood and his colleagues have conducted two tests of the OLF version of IEL, the second an approximate replication of the first. Both studies inquired not only about the effects of IEL on student achievement in math and language but also about the relative influence of a suite of four categories of conditions (12 in total) mediating such effects. Evidence for the first of these studies (Leithwood et al., 2010) were survey responses from 1445 teachers in 199 elementary schools in Ontario and government-collected achievement data for all students in those schools. Results indicated small but significant total effects of integrated leadership on both measures of achievement. These effects were significantly mediated, to about the same degree, by variables include in three of the four categories of mediators. Especially significant individual mediating conditions included CTE along with the school's academic press and disciplinary climate.

Evidence for the second of these studies (Leithwood, 2020) used data from 2017 teachers located in all elementary schools in six Texas school districts, along with school-level student achievement results on a multi-subject state test. The same four categories of mediators were measured in this study as in the first of these studies. Confirming results from the first study, results demonstrated small but significant effects of integrated leadership on student achievement. As in the first study, these effects were largely mediated by CTE, school academic press and disciplinary climate. Broadly similar results also have been reported by Boberg and Bourgeois (2016), Heck and Hallinger (2014), Sebastian and Allensworth (2012), and Day et al. (2016).

The ninth and final study in this review was by Kwan (2020) using responses from vice-principals in 177 Hong Kong schools to assess IEL effects on student outcomes and the interaction of TL and IL in producing those outcomes. The measure of TL in Kwan's study included items (15) classified as *strategic directions and policy environment, leader and teacher growth and development, and staff management* (broadly defined), while the measure of IL included items (10) classified as *Teaching, Learning, and Curriculum and Quality Assurance and Accountability*. Results indicate that the influence on student achievement of two of the three components of instructional leadership (quality assurance and accountability, teaching, learning and curriculum) were significantly moderated by transformational leadership. Kwan concluded that:

Instructional leadership by the principal will not lead to considerable improvement in student outcomes unless the principal has already made available a school environment in which teachers are competent and motivated (p. 344).

The nine studies reviewed in this section of the paper indicate, in sum, that IEL has generally positive effects on the quality of classroom instruction, as well the engagement and achievement of students in several different disciplines. These effects are mediated by a small number of school conditions, most notably the collective efficacy of teaching staffs, a strong academic school culture and a safe and orderly environment/disciplinary climate for both staff and students.

Nevertheless, this body of evidence places severe limitations on claims that can be made about IEL effects. First, it is a very small body of evidence. Second, only three of the studies compared the relative effects of IL and TL components and demonstrated that the two components together have larger effects than either component separately (Kwan, 2020; Marks and Printy, 2003; Day et al., 2016). Finally, conceptions and measures of IEL varied widely. Only three of the eight studies provided evidence about approximately the same model of IEL. The most defensible conclusion to be drawn from this evidence, as a whole, is that IEL has the potential to realize the values conceptualized for it but, to invoke that well-worn phrase "more research is needed".

Improving conceptions of integrated leadership: adding "personal leadership resources"^c

Most accounts of IL focus exclusively on the overt behaviors or practices of those exercising leadership, with only modest attention to the feelings, emotions or dispositions of either leaders or their colleagues. Accounts of TL acknowledge the central importance of leaders engaging with the dispositions of their colleagues but are largely silent on the dispositions of leaders themselves. Neglect of attention to leaders' dispositions has been influenced to a great extent by early leadership research casting doubts in the contribution of dispositions or traits to explanations of variation in leadership effectiveness (e.g., Stogdill, 1974). The warrant for excluding traits, however, began to be challenged in the 1980's (e.g., Kenny and Zaccaro, 1983) and by 2007 Zaccaro, for example. Noted that:

A number of studies have linked personality variables and other stable personal attributes to leader effectiveness, providing a substantial empirical foundation for the argument that traits do matter in the prediction of leader effectiveness (p. 6).

Considerable evidence now substantiates this argument (e.g., Judge et al., 2002; Peterson et al., 2003). Furthermore, as Zaccaro also claims, the "qualities that differentiate leaders from non-leaders are far ranging and include not only personality attributes but also motives, values, cognitive abilities, social and problem-solving skills, and expertise" (2007, p. 8). Taken as a whole, these personal qualities help to explain why leaders differ in their responses to the same situations or contexts. Personal resources heighten leaders' attention to selected features of the situations they face, sometimes triggering predictable response among those with similar personal resources (Gottfredson and Reina, 2020).

These strands of theory and evidence prompted the addition of four categories of personal leadership resources to the OLF - cognitive, social, and psychological resources, along with values and ethics - introduced here to exemplify the value added to conceptions of IEL by introducing leader dispositions.

Cognitive resources

Considerable evidence collected over many decades suggests that leaders' success or effectiveness is partly explained by intelligence and experience. This would only be surprising if it was not the case, although some early evidence indicates that stressful and hectic

^cThe term *Personal Leadership Resources* is used here (and in the OLF) to encompass traits, dispositions and other "internal" qualities of leaders.

environments (features of environments in which school leaders often find themselves) reduce the advantage of greater intelligence to near zero. Intelligence and experience, however, are “surface” traits of leaders offering little guidance to those selecting and developing leaders or to leaders and aspiring leaders themselves. Below the surface of what is typically referred to as leader’s intelligence are problem-solving capacities and below the surface of “experience” is the domain-specific knowledge useful for such problem solving.

Problem solving expertise

Problem solving is at the heart of leaders’ day-to-day work (Kelman et al., 2020) and effective IEL practices, whether of the IL or TL variety, can be viewed as the “solution processes” component included in most comprehensive problem-solving models. Research on expert problem solving is extensive and there are multiple possible models that could be included as part of an IEL model (e.g., Mumford et al., 2007).

The main components of the model included in the OLF, for example, include problem interpretation, identification of constraints, goal setting, clarification of relevant principles and values, identification of possible solutions, and considerations about how the mood of problem solvers influences their decisions. This problem-solving model is the outcome of a decade-long program of research on how expert school and district leaders solve unstructured problems (e.g., Leithwood and Steinbach, 1995).

“Systems thinking” is also a form of problem-solving writ large. Leaders able to engage in systems thinking understand the dense, complex and reciprocal connections among different elements of the organization; these Leaders also exhibit the foresight needed to engage their organizations in likely futures and consequences for action (Shaked and Schecter, 2017). Changing one organizational element typically has consequences for many others. These consequences may be positive or negative. So, leaders engaged in improvement efforts also need to anticipate and take into account possible second-order consequences of their planned improvements.

Organizational improvement knowledge

While is not possible to codify all of the knowledge likely to be useful to those exercising leadership, the well-documented indirect influence of leadership on students recommends priority to “organizational improvement knowledge”. Leaders’ contributions to the success of their students depends on them knowing about those malleable learning conditions in and around their schools with direct positive effects on student success, diagnosing the status of those conditions in their own schools; selecting those most likely to be constraining student success and improving the status of those conditions.

The studies of IEL effects reviewed earlier provided examples of malleable learning conditions with direct effects on student success – an academic culture of high expectations, collective teacher efficacy and a safe and orderly environment. The OLF, for example, identifies twelve of these malleable learning conditions recommended for leaders’ attention by the results of significant bodies of research.

Social resources

The ability to develop and sustain productive working relationships has long been acknowledged as fundamental for leaders in almost all organizational contexts. Socio-emotional skills are also fundamental capacities for nurturing creative leadership in an organization. (Mumford et al., 2007). However, the importance of this ability grows with the interpersonal intensity typically experienced within an organization and the demands such intensity places on its leadership. Schools typically experience a level of interpersonal intensity virtually unmatched in any other type of organization. The capacity of especially school leaders to do such emotionally laborious work depends on their “social intelligence”, “social appraisal skills” or “emotional intelligence” (Slaski and Cartwright, 2003; Schutte et al., 2013). Three types of these social resources, closely aligned with Mayer and Salovey (1997) theory of emotional intelligence, are especially important contributions to leaders’ work.

Perceiving emotions

This set of social resources includes the ability to detect, from a wide array of clues, one’s own emotions (self-awareness) and the emotions of others. People with this relational resource are able to recognize their own emotional responses and how those emotional responses shape their focus of attention and influence their actions. They are also able to discern the emotions being experienced by others from, for example, their tone of voice, facial expressions, body language and other verbal and non-verbal information.

Managing emotions

This set of social resources includes managing one’s own and others’ emotions, including the interaction of emotions on the part of different people in pairs and groups. People with this relational resource are able to understand the reasons for their own “intuitive” emotional responses and are able to reflect on the potential consequences of those responses. Leaders with this capacity are also able to persuade others to be more reflective about their own “intuitive” emotional responses and to reflect on the potential consequences of those responses (e.g., Little et al., 2016).

Acting in emotionally appropriate ways

This set of social resources entails the ability to respond to the emotions of others in ways that support the purposes for the interaction. Leaders do this by exercising a high level of cognitive control over which emotions are allowed to guide their actions and by assisting others to act on emotions most likely to best serve their interests (e.g., [Burch, 2013](#)).

Psychological resources

Three psychological traits (discussed below) make significant contributions to leaders' success individually. But when these resources act in synergy, that is, when one person possesses all these resources, they make an especially large contribution to such success.

Optimism and resilience

Optimism and resilience are closely associated traits. Optimism is the habitual expectation of success in one's efforts to address challenges and confront change now and in the future. At the core of resilience is the ability to "bounce back" from failure and even move beyond one's initial goals while doing so. Resilient leaders have the ability to thrive in the challenging circumstances commonly encountered by school leaders. Optimistic and resilient leaders expect their efforts to be successful in relation to those things over which they have direct influence or control but not necessarily to be powerful enough to overcome negative forces in their organizations over which they have little or no influence or control; they are realistic as well as optimistic. Optimistic leaders are likely to take initiative and responsible risks with positive expectations regardless of past problems or setbacks (e.g., [Avey et al., 2011](#); [Zeni et al., 2016](#)).

Self-efficacy

Sense of efficacy is a belief about one's own ability to perform a task or achieve a goal. It is a belief about ability, not actual ability. That is, efficacious leaders believe they have the ability to solve whatever challenges, hurdles or problems that might come their way in their efforts to help their organizations succeed. Self-efficacy beliefs contribute to leaders' success through their directive effects on leaders' choices of activities and settings and can affect coping efforts once those activities are begun ([Bandura, 1997](#)). Efficacy beliefs determine how much risk people will take, how much effort they will expend and how long they will persist in the face of failure or difficulty. The stronger the self-efficacy the longer the persistence.

The combined effect of Optimism, Resilience and Efficacy is characterized by confidence about succeeding, having positive expectations about succeeding now and in the future, persevering to meet those expectations and being resilient in the face of challenges that threaten success ([Luthans et al., 2004](#)).

Proactivity

Among the personal leadership resources in the *Ontario Leadership Framework*, proactivity alone reflects much of the evidence about the contribution that personality traits make to the explanation of variation in leadership practices; its effects are also an extension of those associated with optimism. Recent evidence about leaders' personality traits has been largely guided by the "five factor model of personality" including Extraversion, Openness to Experience, Agreeableness, Neuroticism and Conscientiousness. Results of this research point to Extraversion as a key contribution to both leader effectiveness and leader emergence (e.g., [Judge et al., 2002](#)). While the contribution of Extraversion to leadership is well established, the concept itself has negative connotations, especially in cultures which value collaboration and leadership distribution. Proactivity is a closely related but more socially palatable trait in such cultures. Emerging from positive psychology, [Crant and Bateman \(2000\)](#) describe Proactivity as follows:

People who are proactive effect environmental change; they identify opportunities and act on them, show initiative, and persevere until they bring about meaningful change. They transform their organization's mission, find and solve problems, and take it upon themselves to have an impact on the world around them. Less proactive people show little initiative, tending to passively adapt to their circumstances rather than change them (p. 65).

Values and ethics

Many decisions faced by leaders are ethical dilemmas ([Cranston et al., 2014](#)) and almost all decisions are influenced, one-way or another, by leaders' values. Considerable evidence associated with ethical leadership points to both personal and professional values influencing leaders' success. Personal values that evidence collected in Western contexts suggests are generally associated with ethical leadership ([Cranston et al., 2014](#)) include, for example: fairness, honesty, integrity, openness, altruism and commitment to the common good. Such values also include trustworthiness and respect for others.

Among the most consequential professional values held by successful educational leaders are belief that the best interests of all students should be at the center of decision making (e.g., NPBEA ISSLC standards, 2015). Other widely endorsed professional values include:

- Social justice and the equitable treatment of students no matter their economic conditions, sexual orientation, cultural and ethnic background or religious affiliation.

- Commitment to high standards of leadership practice.
- Commitment to act ethically and professionally in one's personal conduct and all aspects of one's leadership to the benefit of all stakeholders.
- The responsibility to safeguard and promote the values of democracy, individual freedom and responsibility, equity, social justice, community, and diversity.
- The responsibility to provide moral direction for all members of the organization, the district's staff and elected Board.

These professional values reflect, in education contexts, accounts of ethical leadership reviewed in Freeman et al. (2006). Most are also a direct reflection of values embedded in current educational policy priorities for which school and district leaders are responsible as, for example, a commitment to equity and social justice and the primacy of students' best interests.

Conclusion

This paper has explored the meaning of integrated educational leadership (IEL), reviewed a significant sample of evidence about the effects of IEL on student outcomes, and pointed to a small handful of conditions mediating the effects of such leadership on those outcomes. The *Ontario Leadership Framework* has been used to illustrate possible key features of IEL models, as well as to demonstrate the value of adding "personal leadership resources" or dispositions to models of IEL which are currently limited to the combination of instructional and transformation leadership practices. This addition extends the proportion of leaders' actual work significantly beyond the narrow representation of that work accounted for by most leadership models and begins to explain variation across leaders in their responses to the same context or situation.

Introduction

Deliberations about educational leadership tend to be person-based or place-based. We write about teacher leadership, principal or headteacher leadership, student leadership, and so on. We study department leadership, school leadership, and increasingly system leadership. *Yet*, educational leadership is neither place nor person bound. While what a principal or headteacher does is important to educational leadership as experienced by students, parents, and school staff, it rarely matters in isolation. It interacts with other actors and artifacts within and beyond the school, implicating a wide variety of people and organizations. Framing educational leaderships as a systemwide phenomenon focuses attention on how leadership practice is constituted in the interactions among actors (assistant principals, teacher leaders, system leaders, students, parents, teachers) and artifacts that stretch from the classroom to the principal's office and beyond to the system hub whether that is a Local Educational Authority, a provincial or ministry of education, or IB central. Our article sketches a multilevel distributed framework for doing diagnostic, design, and development work about educational leadership that embraces the *systemwide* nature of the phenomenon.^a

We outline and argue for a multilevel distributed framework in order to explore educational leadership *systemically*; that is, as a *systemwide* phenomenon. Our approach should not be confused with arguments for studying system leadership, though we agree with such arguments and incorporate systems into our discussion. Rather, system leadership is just one level of consideration in the multilevel distributed framing we develop in this article. Our multilevel distributed perspective also takes into account that actors and artifacts stretched across multiple levels of education systems may interact in different ways depending on the particular educational system and the national educational sector in which the system operates. Our framework enables comparative work on educational leadership.

Our article is organized like this: We begin by motivating and anchoring our work in research in the distributed leadership tradition. We then outline the elements of our multilevel distributed framework for thinking about educational leadership. We do so by anchoring our framework in teaching which is the core technology of education systems. We then map backwards from the classroom sketching a multilevel framework that takes the school, community, educational system, and educational sector into account. We conclude with a discussion of the entailments of the framework for diagnostic, design, and development work on educational leadership.

Some discussion of the construct of leadership is always wise at the outset, as there is no shortage of definitions. Definitions of leadership and attempts to operationalize them for diagnostic, design, and development work vary widely. Indeed, people often do not explicitly discuss their definitions of the construct. So, in an effort at clarity at the outset we offer a working definition of leadership and educational leadership in particular. By educational leadership we mean social relationships or interactions tied to the core work of schooling—teaching—that are intended or understood to influence the motivation, knowledge, affect, and practice of educational stakeholders including teachers, students, parents, school and system staff, and others who have a stake in the educational sector (Spillane, 2006; Bass, 1990). Defining leadership in this way anchors our discussion of the phenomena in supporting, improving, and maintaining the quality of teaching, the core technology of educational systems, something we return to in the next section.^b

^aWe include empirical research under diagnostic work. We use diagnostic rather than research in order acknowledge that an array of actors in the education sector do diagnostic work though for many it would not count as empirical research. Yet such work is critical to education and its improvement.

^bThere may be other important ways that school leaders can improve outcomes beyond teaching and learning, such as through building social relationships between the school and community institutions. However, we put aside such other functions to focus on the core enterprise of schooling—teaching and learning.

Educational leadership framed from a distributed perspective

One development in the field of educational administration and leadership over the past few decades involved attention to the practice of leadership; that is, how the work of leadership is actually accomplished inside school. Some work on practice centers on understanding the actions or behaviors of individual school leaders, especially head teachers or principals (Blase and Blase, 1998, 1999; Blase and Kirby, 2000). Others have argued for framing practice differently, not simply a matter of the actions or behaviors of individual leaders but centered on those interactions that are the essence of social influence relationships. Framed from a distributed perspective, educational leadership involves two essential components aspects; first the practice aspect from which the second aspect—the leader-plus—follows (Spillane, 2006; Spillane et al., 2008; Spillane and Ortiz, 2016; Spillane, 2020).

The practice aspect foregrounds the *practice* of leadership – *leading* – and frames our attention on what leaders and followers actually *do together* and how they do it. From a distributed perspective, practice is framed in a particular way: Drawing on activity theory, distributed cognition and socio-cultural activity theory (Hutchins, 1995a, 1995b), a distributed perspective frames leadership practice as unfolding in the interactions among people as these interactions are enabled and constrained by aspects of their situation. A distributed perspective sees practice as taking shape in the interactions among leaders and followers (acknowledging that people move in and out of these roles), and aspects of their situation such as tools, routines, norms, regulations, and so on (Gronn, 2002; Spillane et al., 2001, 2004; Spillane, 2006). To understand the practice of educational leadership from a distributed perspective we have to get beyond an exclusive focus on the actions of individual leaders and get to the *interactions* among them. From a distributed perspective, aggregating the actions individual leaders to understand leadership practice is insufficient because people (teachers, school administrators, parents, students) co-enact leadership practice in their everyday interactions with one another.

From a distributed perspective, the situation is afforded an especially prominent position in that interactions among people in schools are fundamentally defined – enabled and constrained – by aspects of their *situation*. Often, the situation is framed as the stage on which leaders' practice and when aspects of the situation are taken into consideration, they are typically cast as aids or accessories to practice that enable educational leaders to work more or less efficiently or effectively. For example, new tools (e.g., data analysis package, online tools for hosting meetings) or organizational routines (e.g., Learning Walks, Instructional Rounds) framed as enabling people to practice in more efficient or effective ways. From a distributed perspective, this conventional approach to framing the situation is inadequate for understanding practice because aspects of the situation are positioned differently in leadership practice as fundamentally defining practice. These often taken for granted aspects of the situation are an essential constituting element of leadership practice because they focus and frame interactions among people in particular ways – who interacts with whom, about what, and how they interact with one another. Viewed this way, aspects of the situation are not external to leadership practice, influencing it from the outside in, moderating or mediating practice, but rather are a core constituting element of that practice similar to leaders and followers. A distributed perspective frames practice as taking place in the interactions among human and nonhuman actors.

By way of example consider two ubiquitous aspects of any organization – organizational routines and tools or artifacts. Organizational routines such as teacher evaluations or supervisions, faculty and grade-level or high school department meetings, school improvement planning, student assemblies, among others, are staples in schools and essential to daily work practice in the schoolhouse. Similarly, tools as externalized representations of ideas that people use in everyday practice (Norman, 1988), such as classroom observation protocols, test score reports, and lesson plans, figure prominently in educational leadership practice. From a distributed perspective, these two aspects of the situation – organizational routines and tools – do not simply influence or accessorize educational leadership practice, but rather define that practice as they are used by school staff in their interactions with one another by shaping who interacts with whom and the substance of their interactions. Aspects of the situation such as tools and routines are never neutral as they privilege some ideas and ways of working and position some organizational members differently (e.g., as experts, with more authority) than others. These often taken for granted and innocuous appearing aspects of the situation reify and reinforce, sometimes challenge, authority and influence social interactions.

The leader-plus aspect follows from the practice aspect recognizing that there are multiple leaders, some of whom may have no formal leadership position, and understanding who they are and how they work is essential. Employing a distributed framework urges us to identify who does the work of educational leadership, that is, who takes responsibility for leading and managing teaching. A distributed framework presses us to move beyond an exclusive focus on the principal and explore how leadership might be distributed across other formal leaders such as assistant principals, teacher leaders, and so on. The framework also allows for individuals with no formal leadership position taking responsibility for educational leadership. From a distributed perspective then, understanding who takes responsibility for educational leadership and how that work is arranged and stretched over people is an important challenge (Spillane, 2006; Spillane and Coldren, 2011).

Educational leadership framed from a multilevel distributed framework

Much of the empirical work taking a distributed perspective has used the schoolhouse as the unit of analysis. While this work has managed to foreground educational leadership practice, it has mostly focused on that practice in the schoolhouse; one might say the horizontal distribution of leadership practice among school staff and stakeholders. As we argue above, however, educational leadership practice is neither place nor person bound. To begin with, schools serve communities that, more or less, organize to exercise influence over education. At the same time, schools typically are part of an education system (sometimes more than one system)

and, more broadly, operate in an educational sector that generates essential resources for schools and sometimes attempt to regulate work in schools. Education systems, some more than others and in distinctly different ways, attempt to guide and support teaching and learning in schools through various means including teacher preparation, student assessments, curricular materials, school inspections, and so on. Depending on the country, the organization of education systems differ as does the extent to which the educational sector is regulated by government or non-government agencies. The organization and workings of education systems and the broader national educational sector are, more or less depending on the system and country, consequential for efforts to lead and manage teaching and learning inside schools. System leaders such as inspectors from a national or provincial ministry of education or instructional coaches from Local Educational Authorities are a potential source of education leadership. Further, many aspects of the situation that are constitutive of leadership practice inside schools are a product of system level design efforts such as school review or improvement routines that are often mandated at the system level. Hence, it is necessary to think about the distributed perspective not just horizontally at the school level, but also vertically across levels of the education system in order to understand how the practice of educational leadership is stretched across classrooms, grade levels, schools, educational systems, and sectors.

Fortunately, research on educational leadership over the past quarter century has moved beyond an exclusive focus on the school-level and the school principal to explore other sources of leadership. Research on teacher leadership makes a case for going beyond the school principal and other school administrators. At the same time, several scholars have shrewdly drawn attention to leadership as a system-level phenomenon. Work in these traditions have contributed to broadening our understanding of educational leadership beyond the schoolhouse. A key challenge that remains, however, is figuring how these various sources of leadership, sometimes operating at different levels and typically studied independently of one another, work in tandem (or not) in an effort to influence teaching. The tendency to compartmentalize leadership by pigeonholing principal leadership, teacher leadership, system leadership and so on, contributes to a disjointed portrayal of educational leadership practice. After all, when it comes to the actual work of teaching and learning, the interrelationships among leadership at different levels is what will matter ultimately for teachers and students, not the independent influence of any one source of leadership.

A multilevel distributed framework seeks to conceptualize leadership as spanning classrooms, school, system, and the educational sector. A core challenge involves figuring how leadership operating at different levels, typically studied independent of one another, work in interaction with each other (or not) to support teaching. Moving beyond focusing on educational leadership at any one level of an education system, such as the grade level, school, district office or ministry levels, a multilevel distributed framework frames the practice of educational leadership as stretched over the interactions of actors and artifacts both within different levels and spanning different levels. It frames educational leadership systemically, as a systemwide phenomenon. A multilevel distributed perspective focuses on how people and aspects of their situation at different levels of the educational interact, not only within but also across levels, to define educational leadership practice. We begin by anchoring the multilevel framework in teaching, the core technology of educational systems, and then engage in a “backward mapping” exercise from classrooms to schools, communities, educational systems, and educational sectors (Elmore, 1979).

Teaching. Any attempt to frame educational leadership as a multilevel distributed practice must engage the challenge of maintaining consistency when working across different levels. We address this challenge by anchoring our multilevel distributed framing in teaching. Differentiating teaching from learning, we argue that teaching is the primary means that education systems have for enabling student learning.^c While student learning may be the ultimate object or goal of educational leadership, we cannot afford to sideline the means that schools and school systems have for getting there – teaching. Educational leadership can enable improvement in student learning in great part by cultivating the conditions that support and maintain the quality of teaching and enable its improvement. In this way, teaching is not only the object of educational leadership it is also its subject.

Teaching as a practice is understood in various ways from the behaviors of the individual teacher to a collective practice co-performed by teachers and students with particular materials. For some, teaching is what the teacher does and says – the actions of the classroom teacher. We embrace a different understanding of teaching, seeing it as a distributed practice, co-performed by teachers and their students as they interact with one another using particular materials (e.g., mathematics, textbooks) (Cohen and Ball, 1999; Cohen, 2011; Delpit, 1995; Freire, 2018). Though the teacher is critical, so are students by virtue of how they interact with the teacher and one another, the ideas they voice, and their ways of being in these interactions. At the same time, how the teacher engages students, both individually and collectively, and treats their ideas and ways of knowing is also constitutive of teaching practice. Teaching is fundamentally about teacher-student relationships that are framed and focused by materials of various sorts, including the school subject. Interactions between teachers and students as they co-perform teaching mathematics or writing are enabled and constrained by the materials they work with including texts, tests, manipulatives, and others.

Framed this way, teaching is a distributed practice stretched over teachers and students and the materials that enable and constrain their interactions with one another, including the cultural resources that students “bring” to the classroom. By participating in cultural practices such as dominoes, dice, basketball, story-telling, rapping, bartering, and dancing, children gather cultural resources that enable them to develop an identity and a sense of belonging (Lee, 1995; Nasir, 2002; Saxe, 1988; Taylor, 2009). But these cultural resources often go ignored, and are sometimes even shunned, in schools and classrooms, contributing to feelings of alienation and not being valued as students (Farkas et al., 1990; Nasir and Saxe, 2003). Students’ ideas and ways of knowing often are seen by teachers as “deficit” (Ainscow, 2005; Clycq et al., 2014; Garcia and Guerra, 2004; Valencia, 2012). When teachers fail to

^cSee Cohen, 1988.

notice and recognize the cultural resources that students have developed from their everyday experiences at homes and in their neighborhoods, resources that could support teaching practice go untapped and unused in teaching. Teaching then is an *embedded* practice in that relationships among teachers and students in the classroom are fundamentally shaped by relationships with others beyond the classroom such as children's relationships with peers in their neighborhoods or with siblings and parents; relationships that involve everyday experiences with numeracy, literacy, science, and nature that do not evaporate once students enter the classroom and co-perform teaching with their teacher.

Relationships and Resources for Teaching. While relationships among teachers and students are fundamental to teaching, we also see educational leadership as fundamentally about relationships; that is, cultivating and channeling relationships that access and activate resources for supporting teaching as a distributed practice. Whereas cultivating relationships refers to strategically initiating and developing them, channeling relationships denotes focusing and directing these relationships substantively. Accessing resources is chiefly about building, procuring, and distributing resources whereas activating resources refers to noticing and using resources in practice. Though the two are closely interrelated, distinguishing between access and activation draws attention to the fact that resources often go unrecognized as such and unused in practice (Cohen et al., 2003). As noted above, teachers sometimes fail to recognize their students' cultural resources and thereby fail to activate these resources in co-performing teaching with students.

Embracing the embeddedness of teaching as a distributed practice acknowledges that the relationships and resources critical for supporting teaching extend beyond the classroom and even the schoolhouse to relationships with, and among, an array of other stakeholders such as parents, community members, neighborhood organizations, educational system leaders, among others. These overlapping and interacting relationships are critical because they shape the resources that teachers and students have access to and condition what teachers and students notice (and thereby activate) and the choices they make in the classroom influencing how they co-perform teaching.

Educational Leadership in The Schoolhouse. The work of educational leadership involves strategically cultivating and channeling relationships that support accessing and activating those resources essential for teaching. The relationships that support accessing and activating resources essential for teaching practice don't just happen naturally (Bourdieu, 1986). Yes, teachers interact with one another, but these interactions often are only tangentially about teaching (Coburn and Russell, 2008). Consistent with a distributed perspective, we focus on the practice of educational leadership and acknowledge that practice is not confined to the principal's office or school faculty meetings, but occurs throughout the school as administrators, teachers, coaches, and many others engage in leadership practices. Though schools are relatively flat organizations, educational leadership unfolds within and across levels of the school organization; it is a multi-level phenomenon as formal and informal school leaders engage in cultivating and channeling relationships that are essential for accessing and activating resources for teaching.

Research suggests that the school's formal organizational arrangements, such as leadership positions and grade level assignments, shape social networks in schools (Moolenaar et al., 2011; Spillane et al., 2015). Teachers of the same primary schools grades, for example, are much more likely to interact with one another about their teaching (Spillane et al., 2015; Spillane et al., 2012). Similarly individuals, including regular classroom teachers, who have a formal leadership position, or teachers who report having more professional development on teaching a particular subject are more likely to be sought out by their colleagues for teaching advice (Spillane et al., 2017). Educational leadership can shape relationships among school staff about teaching in ways that contribute to accessing and activating resources for teaching. School leaders can strategically cultivate new relationships among staff by formally assigning new staff members a mentor or coach. A principal or lead teacher can cultivate relations informally by connecting a teacher who is struggling with teaching a particular subject or unit with a successful colleague in that subject or unit. In this way, school leaders strategically broker relations among their colleagues. Formal and informal brokering of relations among staff, however, must be strategic to contribute to building, accessing, and activating resources. Simply creating a new formal position does not mean that relationships will automatically form around the person in that position as intended (Daly et al., 2010). Some school leaders may be better positioned in their school's relationship network to cultivate particular sorts of relationships. Teacher leaders who teach full or part-time, for example, seem to play more prominent roles in brokering relations among teachers about teaching than full-time administrators such as principals and deputy principals (Spillane et al., 2010).

Cultivating supportive staff relationships about teaching, however, involves more than designing routines and creating positions that bring teachers together regularly. Several other conditions have to be met if these relationships are to genuinely contribute to accessing and activating resources for teaching. To work together productively teachers and staff need to develop norms such as trust (Bryk and Schneider, 2002). Without trust, teachers are less likely to engage openly and honestly with one another about their teaching, the sorts of interactions that contribute to the development of new knowledge about teaching that can contribute to improving teaching practice.

Cultivating and channeling relationships for accessing and activating resources to support teaching in the schoolhouse depend in important measure on a reasonably clear and well-developed shared vision for what and how students should learn (Anagnostopoulos and Rutledge, 2007; Cobb et al., 2018; Leithwood et al., 2004). If the curriculum and teaching strategies intended to support it are ambiguous and ill-defined, or if school staff hold radically divergent views, then cultivating and channeling relationships that support teaching is difficult as teachers and school leaders are pursuing different educational goals. Similarly using different curricular materials, texts, and student assessments among classrooms makes cultivating deep, productive relationships about teaching among teachers difficult. Teachers negotiate understandings about teaching developing new knowledge as they use shared materials and deliberate about their use in their classrooms (Lampert et al., 2011). Curricular materials are important for teachers' joint work outside the classroom as they work together to develop resources (Ball and Cohen, 1996; Davis and Krajcik, 2005; Davis et al., 2014).

Shared visions for instruction, shared materials, and shared expectations for student learning are essential because they help coordinate the work of cultivating and channeling relationships for accessing and activating resources to support teaching. The linchpin of coordination is a clear, shared, and mutually acknowledged vision for instructional practice. It entails well-articulated beliefs about high-quality instruction, norms of professionalism, and ambitious, but achievable, goals for improving teaching. Coordination supports two critical factors that enable high-quality instruction; coordination fosters coherence in how human, social, material, and cultural resources are used (Cobb et al., 2018; Newmann et al., 2001), and it provides direction, motivation, and morale by challenging process of instructional improvement (Bryk et al., 2010; Hallinger, 2011). Coordination is about much more than all school staff getting on the same page and saying, doing, and valuing the same things in an effort to send consistent messages to students, teachers, and other stakeholders. It is about getting the material, social, human, and cultural resources into a generative and interactive system support high-quality instruction (Lampert et al., 2011).

The coordination challenge is in great part about structuring interdependencies among relations and resources in ways that support teaching practice—and maintaining that structure over time. To help conceptualize this, we use the idea of an *infrastructure*, connoting a set of entities and the relationships among them required for the operation of an enterprise. An *educational infrastructure* consists the structures and resources that educational systems develop, intended to support and coordinate teaching, maintain its quality, and enable improvement (Cohen et al., 2013, 2018; Hopkins et al., 2013; Peurach and Neumerski, 2015; Spillane et al., 2019). Much of the work of creating an educational infrastructure occurs outside the schoolhouse, though it varies depending on the national educational sector and the educational systems. At the same time, school leaders' access to key resources for supporting teaching, such as skilled and knowledgeable teachers, depends on circumstances beyond the schoolhouse even in the same educational sector. As several studies document, access to quality teachers differs substantially for urban schools compared to suburban schools. Further, in some national educational sectors either a government agency or a national ministry of education exercises influence over who gets to teach and the content of their teacher preparation (e.g., Ireland) whereas in other situations such matters are left to universities with only minimal oversight (e.g., US).

For all these reasons educational leaders in schools depend on their environments for not only access to, but also the coordination of all sorts of relationships and resources that are essential for supporting teaching in schools (Scott and Davis, 2015). Hence, the importance of taking a multilevel distributed framework to research on educational leadership.

Schools and "National" Educational Sectors. Scholars frame the environments in which schools and other organizations operate as organizational fields or, more commonly, as educational sectors. A sector – such as the health sector or the education sector – consists of the set of actors and organizations operating within a given domain, supporting those who provide a product or service. We can think of schools as the focal organizations in the educational sector, but we also have to pay attention to the array of ancillary actors – organizations and individuals – that are critical to the work of schooling. The educational sector comprises a hodgepodge of actors and organizations in addition to schools and educational systems, including government agencies, professional development providers, community and professional organizations, unions, philanthropy, research firms and institutes, supplemental educational providers, and others. These organizations typically do not directly provide schooling but play a supportive role in providing resources (human, social, material), sometimes directly in school or classroom practice (Rowan, 2002). Other organizations serve regulatory functions regarding resources (e.g., curricular materials) and services (e.g., teacher preparation). In some educational sectors, the same organization performs more than one of these functions.

The in-school relationships that are essential for accessing and activating resources are embedded in relationships that extend beyond the schoolhouse to the educational sector. These sectoral organizations are critical to cultivating and channeling relationships that access and activate resources. Indeed, the work of designing, deploying, and maintaining an educational infrastructure involves various actors and organizations in an educational sector, not just schools. Depending on the particular national educational sector and the decisions of regulatory agencies, the presence, form, and role of these organization can vary. These ancillary organizations can influence the work of leadership in the schoolhouse and beyond by shaping the resources school leaders and teachers can access and support the use of resources in practice (Coburn, 2005).

Schools depend on the educational sector in which they operate for legitimacy, and for other essential resources to improve the quality of teaching, and address inequities in students' opportunities to learn. How schools are embedded within an educational sector is a critical consideration for educational leadership in the schoolhouse because it shapes which resources are available, how they can be accessed and their use supported in practice. Governmental organizations may regulate the training and certification of teachers and other professional staff—or this essential resource for teaching may be delegated to quasi-governmental organizations. Alternatively, the training and certification of teachers may go mostly unregulated or with minimal government oversight. Organizations in an educational sector produce and distribute various resources – some provide curricular materials, others develop, administer, and score student assessments, others provide pre- and in-service professional preparation and development. In some national sectors, government and/or non-governmental organizations work to regulate the efforts of these organizations and their provisions. These variations are consequential for leadership in the schoolhouse because they contribute to differences in the work and the challenges that school leaders face as they attempt to cultivate relationships with various organizations in the sector toward supporting teaching.

Some organizations in an educational sector are transnational, raising the question of how to define boundaries. Examples are publishers such as Pearson or organizations that design and administer international student assessments (e.g., PISA), the Organization for Economic Cooperation and Development (OECD). Some educational systems operate across various national educational sectors such as International Baccalaureate and AMI Educational. Although organizational fields are often not constrained by national borders, because of distinct differences among nations, we believe it is useful to think about them, for analytical

purposes, in terms of national educational sectors. A nation's regulatory agencies often have the power to shape the educational sector by authorizing who can provide particular services within national borders.

Schools, Sectors, and Educational Systems. Educational systems are involved, in various ways and to varying degrees, in coordinating the design, deployment, and support of educational infrastructure. Often the terms "school system" and "educational system" are used interchangeably; however, we see them as capturing an important analytical distinction: they refer to different ways of organizing (Peurach et al., 2019; Spillane et al., 2019a,b). An educational system is concerned with the educational function of schooling and schools; it is focused on supporting the day-to-day teaching and learning in schools. Educational systems include the set of central organizations that drive efforts to support instruction and its improvement; these could include district offices (or teams within the office), charter management organization, a diocese office, or even a national or provincial ministry of education (Peurach et al., 2019). System roles and responsibilities can overlap, spanning national, state and provincial governments; some schools belong to two or more educational systems, such as when a local public school district adopts International Baccalaureate. We use "school system" to refer to organizations at the national or regional levels with the legal authority to provide schooling by building and operating schools, sorting students into schools and classrooms, and resourcing classrooms with teachers and sometimes instructional materials. Analytically, the key distinction between school systems and educational systems is that the latter establish the vision for learning and improving instruction, build and coordinate resources to support the vision in school, and addressing inequalities in students' opportunities to learn (Peurach et al., 2019).

There are also religion or faith-based and independent systems which operate with various degrees of government regulation or quasi-government regulation depending on the national educational sector and the particular system. In some countries, national or provincial government ministries regulate all school systems receiving public funding. In others, there is limited government regulation and limited public funding for such systems. Finally, there are international educational systems, like Montessori and the International Baccalaureate, which operate schools with varying levels of involvement from governmental entities depending on where the national educational sector in which they operate. Though educational systems take different forms, they typically include schools and some central agency or hub that more or less manages the core educational functions.

One way in which educational systems matter to educational leadership is that they attempt (some more eagerly and comprehensively than others and in different ways) to coordinate the resources and relationships essential for supporting teaching. Educational systems coordinate the designing and building of educational infrastructures, work to support the use of that infrastructure in school and classroom practice, and manage educational infrastructure and its use in order to improve and maintain the quality of teaching and reduce inequities in opportunities to learn (Peurach et al., 2019; Spillane et al., 2019a,b). Educational infrastructure includes instruments and tools that are the material of teaching, such as curricula and student assessments. It also includes the formal positions, procedures, organizational routines, and tools that educational systems design, acquire, and deploy to support teaching and its improvement. Further, it includes the coordination of core educational functions, including building a technical culture anchored in consistency among the components of infrastructure, and representing a shared vision for teaching and learning. Other core functions include recruiting and hiring professional staff, teacher educational and ongoing professional learning for staff, monitoring teaching quality, and leadership and management and improvement of teaching.

Education systems vary in how the design and deployment of infrastructure is achieved. In some nationalized and centralized systems, a central or provincial ministry often takes a prominent role. In other educational systems, central offices may play a more modest role, leaving the building, maintaining and supporting of educational infrastructure to schools. The work of leadership in schools varies significantly.

In thinking about educational leadership then, we must also take the educational system into account. People in educational systems perform key leadership functions and take on important responsibilities, such as articulating a coherent vision for teaching and learning and for improving teaching. Systems leaders develop, provide access to, and support the use of critical resources, such as curricular materials or professional development (Cobb et al., 2018). The extent and quality of work by system leaders, and how they are organized (managerial, market, federated, networked), has important impact for leadership in the schoolhouse. Further, depending on the country several different educational systems may operate in any one national educational sector. As a result, simple cross-national comparisons of educational leadership are problematic as the work and challenges can differ depending on the educational system and how the national educational sector is organized.

The type of educational system(s) a school belongs to shapes the coordination among actors and organizations in the sector. Some schools are a part to more tightly coordinated centralized systems where much of the work of designing and deploying an infrastructure is done by central offices. Leaders in schools may therefore rely less on other ancillary organizations to access and activate support. In contrast, some schools exist in systems where school leaders shoulder much of the responsibility for reaching out to other organizations in the sector to secure instructional materials or professional training. Charter schools in the United States are an example.

Above, we frame educational leadership in the schoolhouse as a distributed practice; that is, educational leadership is constituted in the interactions among school staff as they are enabled – or constrained – by key aspects of their situation. Educational infrastructure is a critical aspect of that situation. In other words, the nature of an educational system's infrastructure defines the practice of educational leadership in the schoolhouse differently as it focuses and frames interactions among school staff, students, and other stakeholders.

Designing and deploying an educational infrastructure involves multiple actors and organizations across the sector; which actors and organizations and how they are arranged varies depending on the system and the national educational sector. Further, some education systems take a more central role than other systems in designing and deploying educational infrastructures and

supporting the use of those infrastructures in school and classroom practice which is critical for coordinating the resources and relationships essential for supporting teaching. This underscores the importance of taking a multi-level perspective by thinking about leadership as extending over the school and the educational system – and indeed over the educational sector more broadly. This is the subject we examine next.

The work of supporting and improving teaching is not solely the province of school leaders, teachers and other professional staff and stakeholders. Schools are typically part of an educational system or systems,^d and embedded in an educational sector that provides essential resources and support. We conceptualize leadership as a multilevel, distributed process, reflecting the collective nature of designing and deploying an infrastructure that involves several organizations. Moving beyond the schoolhouse, our account makes the case for thinking about leadership most broadly from a multilevel distributed perspective.

We expanded our view of educational leadership by recognizing that (1) schools are embedded in multiple critical relationships for improving teaching; and (2) leadership is distributed across the entire sector in order to best coordinate the design, deployment, and use of an educational infrastructure. Focusing narrowly on individual school responsibility misses the array of relationships that school leaders should cultivate to improve teaching. Education systems vary in how they do the work of coordinating resources and relationships fundamental to successful efforts.

Conclusion

A multi-level distributed framework eschews compartmentalizing leadership by pigeonholing principal leadership, teacher leadership, system leadership and so on because such framings contribute to a disjointed portrayal of educational leadership practice. After all, when it comes to the actual work of teaching and learning, the interrelationships among leadership at different levels is what will matter most, not the influence of any one source of leadership independent of the others.

Our article sketched an analytical framework to address two blind spots in current approaches to educational leadership by exploring the interrelationships among different sources of educational leadership operating at various levels, from classrooms, to schools and beyond, to educational systems and the educational sector *and* by elucidating how the practice of educational leadership is not only distributed within the schoolhouse, but also distributed across educational systems and sectors. Our multilevel distributed framework has entailments for work on educational leadership and educational improvement.

Entailments for Leadership Practice and Developing Practice. To engage effectively with the multilevel distributed framing to educational leadership, suggests that aspiring leaders acknowledge the following. First, with a few notable exceptions (DeFlaminis et al., 2016), efforts to develop educational leadership tend to be role bound and individual-centered. Educational leadership development programs, whether pre-service or in-service, rarely distinguish leadership practice from developing individual leaders. We believe programs need to focus more on developing leadership practice. Whether one is a school or system leader, understanding that it is not all about “me” (the individual) is critical; the practice of educational leadership is about the individual in interaction with others, from across the educational system, as enabled and constrained by aspects of their situation. For aspiring practitioners of an effective multilevel distributed process, this is difficult but critical. Teaching, as both the object and subject of educational leadership, provides an important anchor for working on educational leadership. Educational leadership development must also focus more on preparing leadership teams to engage in the twin processes of diagnosis and design thinking (Breakspear et al., 2017).

Entailments for policy. Educational policymakers in several countries are paying more attention to leadership, perhaps in part because of a growing concern about the quality of teaching and inequalities in students’ opportunities. Educational policymakers in some countries are introducing certification requirements for school leaders, in particular school principals and head teachers. Several governments have introduced legislation that hold the school principal or head teacher accountable for school performance, often as measured by a handful of metrics, typically student performance on standardized tests and attendance. Policymaking on educational leadership tends to target leadership in the schoolhouse, and mostly fixates on the school principal or head teacher. Our multilevel distributed framework suggests that caution is in order regarding these policy initiatives; if policymakers sincerely wish to legislate action to improve educational leadership (whether they should or not is a different issue), they should to adopt a more comprehensive approach as outlined and described in our text.

With respect to policymaking that addresses certification, preparation, and advancement of educational leaders, a systemic approach that focuses on both the educational system and schoolhouse leadership together is essential. A comprehensive policy approach to leadership advancement should attend to everyone from teacher leaders to school administrators and system leaders. Moreover, it should accommodate non-linear movement among positions so that, for example, a deputy head or assistant principal with an opportunity to take a system leadership position could also have the flexibility to move back to a school leadership position.

Entailments for research. Applying a multilevel distributed framework to research on educational leadership argues for attention to sources of leadership not only within but beyond the schoolhouse in the educational sector and seek to understand the interdependencies among these various sources for leadership practice. Research must recognize that most schools are part of an educational system(s), and that we should examine the work of educational leadership as part of this system. Adopting a multilevel

^dWe acknowledge that there are independent schools that do not belong to educational or school systems as defined here, but for the purposes of this brief, we do not attend to these schools.

mindset will necessitate examining leadership as a practice that stretches over the broader educational system, and exploring how leadership responsibilities are distributed and managed across different levels from classrooms to the central offices of the system. Such work involves recognizing how educational systems and educational sectors differ around the world and exploring how these sector and system differences contribute to differences in the practice of educational leadership.

Introduction

Distributed leadership represents one of the most influential ideas to emerge in the field of educational leadership, prompted by the foundational and seminal work of [Spillane et al. \(2001\)](#). The idea of distributed leadership has found favor with researchers, policy-makers practitioners and educational reformers around the globe and has captured the attention of many international researchers (e.g., [Spillane, 2006](#); [Harris, 2008](#); [Leithwood et al., 2009](#); [Gronn, 2002](#)). Few ideas, it seems, have provoked so much attention, debate, and controversy, in the field of educational leadership, as distributed leadership.

Unlike many other fashionable leadership ideas, labels, and theories, distributed leadership has stood the test of time and it could be argued has experienced a renaissance during COVID 19 times, where most leadership practice was virtual, remote, and inevitably distributed ([Harris and Jones, 2020](#)). This chapter looks at the two decades of research that followed the [Spillane et al. \(2001\)](#) article on distributed leadership, primarily in the education sector. It looks at the evidence base in two-halves.

Firstly, it draws upon the literature from 2001 to 2011 mapping out the key empirical terrain, taking a retrospective view. Secondly, it offers a new review of the literature from 2011 to 2021 giving a contemporary assessment of the more recent research evidence concerning distributed leadership. The chapter concludes with some thoughts about the next decade of empirical enquiry and considers whether distributed leadership remains a relevant concept for those working within the field of educational leadership.

In 2001, distributed leadership emerged as a *key* leadership idea of that moment along with ongoing interest in instructional and transformational leadership. While the notion of shared, collaborative, or participative leadership was far from new, distributed leadership theory provided a new lens on a familiar theme. The work of [Spillane et al. \(2001\)](#) sparked renewed interest in leadership as *practice* focusing particularly on the interactions between leaders, followers, and their situation. This seminal work on distributed leadership theory reinforced the multiple sources of influence that operate within any organization and focused empirical attention on the *leader plus* aspect of leadership work ([Spillane, 2006: 3](#)). From a distributed perspective, interactions are a critical part of leadership practice. Analyzing and understanding patterns of influence from a distributed perspective, it was proposed, provides a closer and more nuanced understanding the practice of leadership.

From the outset, however, distributed leadership was an idea not devoid of controversy or critique. Writes like [Fitzgerald and Gunter \(2006\)](#) and [Hargreaves and Fink \(2009\)](#) called into question the motivation of those espousing distributed leadership. In their view, distributed leadership was little more than a palatable way of encouraging teachers to do more work, a way of reinforcing standardization practices, simply old managerialism in a contemporary guise. Instead of being a more democratic form of leadership. [Hargreaves and Fink \(2009\)](#) proposed that distributed leadership could in fact be another, more attractive, mechanism for delivering government policy.

In their critique, [Fitzgerald and Gunter \(2008: 335\)](#) suggested that teacher leadership, which is closely associated with distributed leadership, “merely cements authority and hierarchy whereby leaders monitor teachers and their work to ensure set of predetermined standards are met.” They argued “that teacher leadership is deeply rooted in neo-liberal versions of the performing school and that it is a management strategy and not a radical alternative” ([Fitzgerald and Gunter, 2006: 335](#)).

It is important not to lose sight of these critical perspectives even though, in most cases, there was little empirical evidence to substantiate the claims made. Those opposed to distributed leadership largely came from an ideological position, rather than an empirically grounded one (Fitzgerald and Gunter, 2006). Those researching in the leadership field, however, have taken care to point out the shortcomings and limitations of distributed leadership in their writing (e.g., Harris, 2007).

The next section of this chapter offers a retrospective view of the evidence, focusing on the decade following the Spillane et al. (2001) article.

Distributed leadership: a retrospective view

In the decade from 2001 to 2011, it was consistently argued by those writing about distributed leadership that the practice was pivotally important in securing organizational improvement. Knowing if, how and in what way distributed leadership practice influenced organizational outcomes was at the heart of a great deal of contemporary scholarly enquiry during this period (Leithwood et al., 2009). The available evidence also suggested a positive relationship between distributed leadership, organizational improvement, and student achievement (Harris, 2008, 2009; Hallinger and Heck, 2009; Leithwood and Mascal, 2008). Many studies reinforced the importance of distributed leadership as a potential contributor, under the right conditions, to positive organizational change and improvement.

Even though the evidence base about distributed leadership was still emerging, at this time, the concept had already been enthusiastically adopted within educational policy circles in several countries including the UK, USA, Australia, parts of Europe, and New Zealand. Most of these policies took a normative stance on leadership distribution and emphasized extended forms of leadership at school, district, and system level. For example, in Wales, distributed leadership was a key part of the national school effectiveness framework in 2012. In England, distributed leadership featured heavily in workforce remodeling and reform along with the introduction of new models of schooling such as federations, partnerships, networks, and multi-agency working. In the USA, distributed leadership was a feature of many of the comprehensive school reform approaches.

Despite words of caution from those in the research community, distributed leadership was an idea that was widely advocated and endorsed in many education circles around the world. This proved to be both good news and bad news. On the positive side there was evidence to suggest that certain forms of collective leadership or forms of distributed influence “have a modest but significant indirect effect on student achievement” (Leithwood and Mascal, 2008, p. 546). It was also clear, from the available evidence, however, that *how* leadership was distributed mattered greatly. Early research underlined that distributed leadership was not intrinsically a positive or negative thing, rather it depended upon the purpose, form, and nature of the distribution.

As Leithwood et al. (2009) highlighted in their empirical analysis, purposeful or planned leadership distribution was more likely to impact positively on school development and change. Other researchers similarly reinforced that successful leadership distribution occurs by careful design rather than some random default (Day et al., 2009). The empirical work, at that time, highlighted that it was *how* leadership was distributed (i.e., the patterns of distribution) that explained its subsequent impact.

Putting distributed leadership to the empirical test

In the decade that followed Spillane et al. (2001), distributed leadership became a very slippery concept, often moving between theoretical, descriptive, analytical, normative, and applied interpretations. The term was used liberally to mean distinctively different things and such discrepancy in meaning meant that sometimes researchers simply talked past each other (Mayrowetz, 2008: 425). One common misuse of the term was to align distributed leadership with any form of collaboration thus blurring the precise meaning of the term even further.

It was clear from those writing about distributed leadership, at that time, that different conceptualizations and interpretations of the term persisted and prevailed (Harris, 2007). As Mayrowetz (2008) proposed, it was crucial to inventory the multiple usages of the term distributed leadership for two reasons. Firstly, because of the wide variation in meaning and secondly, to make clearer connections between such usages and the goal of organizational improvement. As Leithwood et al. (2009) underlined, there was little to be gained in continuing to debate the rights and wrongs of different positions or perspectives on distributed leadership. Instead, he proposed that the main challenge was to measure the degree and extent of any organizational impact and effect from distributed leadership.

Apart from wandering definitions, another early issue with distributed leadership was its popular positioning as the antithesis of top-down, hierarchical leadership. This misinterpretation proved to be deeply unhelpful. While distributed leadership is essentially an alternative way of understanding leadership practice, to view it simply as the opposite of formal, autocratic leadership is to misrepresent the concept even further. As researchers at the time underlined, distributed leadership encompassed both formal and informal forms of leadership practice within its framing, analysis, and interpretation. As Spillane (2006: 58) clearly noted, distributed leadership involved the “co-performance of leadership and the reciprocal interdependencies that shaped leadership practice.”

Researchers, at the time, continued to investigate two pressing questions. Firstly, what difference, if any, did patterns or configurations of distributed leadership make to classrooms, schools, and school systems? Secondly, how could we know? On the second of these issues, it was clear that the methodological challenges associated with research into distributed leadership were complex

and considerable. The proliferation of accounts of the single, often “heroic” leaders in the leadership literature was largely explained by the methodological ease of data gathering. If leadership equates with role and position, then it is relatively straightforward to collect evidence about the actions and responsibilities of those occupying leadership positions. It is easy to compile case studies based upon the actions, usually self-reported, of individual leaders. Indeed, the leadership literature is replete with such case studies. Alternatively, if leadership is construed as interaction and the aggregate of a complex set of social processes then the methodological challenges increase exponentially.

Without question, it more difficult to investigate distributed leadership empirically because of the multiple sources of influence. But it is not impossible. As Spillane (2006) showed in his extensive empirical work, data collection methods needed to be more sophisticated and nuanced to capture distributed leadership practice. His research work, with colleagues over this decade, demonstrated that it was perfectly possible to collect data about distributed leadership through new research techniques, tools and alternative methodological approaches.

Earlier work by Spillane et al. (2001) focused on the nature of interdependencies and the co-performance of leadership practices in schools. Implicit in the notion of “co-performance” was the possibility that those performing the practices might be pursuing different or even contradictory goals. “From a distributed perspective, leaders can interact in the co-performance of leadership routines even when they seek different or conflicting outcomes” (Spillane, 2006: 84).

But what do we know from the early empirical evidence about distributed leadership? Firstly, we know that the empirical base about distributed leadership could be found in different research fields and traditions. Early studies that offered research informed insights into distributed leadership were contained in literatures pertaining to school improvement; organizational change; teacher leadership and school leadership. This research terrain was diverse but despite the miscellaneous nature of the early evidential base, consistent messages about distributed leadership and organizational change were forthcoming. For example, there was evidence of a positive relationship between organizational change and wider leadership distribution (Harris, 2008; Leithwood and Mascal, 2008).

Secondly, there were a growing number of early empirical studies that focused attention explicitly on the impact of distributed leadership upon teaching and learning (Leithwood et al., 2009). Such studies provided evidence about the nature, form, and impact of distributed leadership practices in schools. Studies by Hallinger and Heck (2009) highlighted a positive relationship between distributed leadership and certain student outcomes. These studies also reinforced a positive impact on teachers’ level of self-efficacy and motivation. Leithwood et al. (2009) concluded that the “field was now much closer to developing impact studies of distributed leadership because of the theoretical, conceptual and empirical work undertaken.” They noted, however, that the major challenge to the field was to start designing such research studies.

Thirdly, early research studies tended to conceptualize distributed leadership as a form of work-redesign and focused on distributed leadership as a form of job re-design or work restructuring (Harris, 2008). Other researchers paid close attention to the different patterns of leadership distribution in schools (Leithwood et al., 2009; Spillane and Camburn, 2006). The main question pursued, at this time, concerned different patterns of distributed leadership that existed in schools and whether, and in what way, if any, they made a difference to organizational outcomes. As noted earlier, generally the empirical findings suggested that the configuration of leadership distribution was critically important and that certain patterns of distribution had a more positive effect upon organizational development and change (Leithwood et al., 2009).

The early evidence proposed that there were different formations of leadership distribution in schools, some were random, some emergent, and some were carefully orchestrated. Leithwood et al. (2009) suggested that there were different patterns of distribution reflecting differing degrees of active alignment and co-ordination. This insightful work reinforced the importance of planned, aligned distributed leadership practice that is purposeful and focused. Other evidence pointed toward the importance of “principal directed” approaches to distributed leadership (Harris, 2008; Day et al., 2009).

The fourth main finding from the early empirical evidence highlighted a relationship between carefully distributed leadership and organizational performance. As already noted, some writers advocated that distributed leadership was in fact a form of work-redesign. The implication arising from this position was that certain forms of work-redesign created key critical psychological states where employees felt more responsible for their work and were given greater autonomy.

The early evidence also reinforced that distributed leadership had a greater impact upon organizational development where certain structural and cultural conditions were in place (Louis et al., 2009). Within this early literature there was the strong implication that distributed leadership had the potential to positively influence organizational change and student outcomes, under the right conditions. The relationship between distributed leadership and student outcomes is considered next.

Distributed leadership and student outcomes

Without question, the relationship between distributed leadership and student outcomes, in the early evidence base, was the most controversial and contested issue. Positions on the relationship between distributed leadership and student outcomes varied. Some writers argued that seeking to explore this relationship was simply a futile exercise. They suggested that the “search for normative links between specific leadership distribution patterns and student achievement results is unlikely to yield clear guidelines for practice”. Conversely, others argued that distributing leadership is only desirable if the quality of leadership activities contributes to “assisting teachers to provide more effective instruction to their students” (Timperley, 2005: 220).

In essence, there were a limited number of studies that explicitly explored the relationship between distributed leadership and important organizational and student outcomes. Two pivotal studies, however, stand out, offering useful insights into the relationship between distributed leadership and student outcomes. The first study by [Leithwood and Jantzi \(2000\)](#) suggested that distributing a larger proportion of leadership activity to teachers had a positive influence on teacher effectiveness and student engagement. They also noted that teacher leadership had a significant effect on student engagement that far outweighs principal leadership effects after considering home family background.

The second study by [Silns and Mulford's \(2002\)](#) also provided empirical confirmation of the key processes through which more distributed kinds of leadership influence student outcomes. Their work concluded that student outcomes are more likely to improve when leadership sources are distributed throughout the school community and when teachers are empowered in areas of importance to them.

There was other early, empirical work that demonstrated a positive relationship between distributed leadership and student outcomes. A study of teacher leadership conducted in England found positive relationships between the degree of teachers' involvement in decision making and student motivation and self-efficacy ([Harris and Muijs, 2004](#)). This study explored the relationship between teacher involvement in decision making within the school and a range of student outcomes. These findings showed a positive relationship between distributed leadership and student engagement.

[Camburn and Han \(2009\)](#) explored the outcomes of distributed leadership by drawing upon extensive evidence from an investigation into the America's Choice CSR program. A core design feature of this program was the requirement to distribute leadership responsibilities to teacher leaders in schools to act as a key lever for instructional change. Their research work outlined the impact of this program in 30 urban elementary schools and investigated the association between the distribution of leadership to teachers and instructional change. This study concluded that distributing leadership to teachers can support positive instructional change under the right conditions.

[Hallinger and Heck \(2009\)](#) explored the impact of system policies on the development of distributed school leadership and school improvement. Their quantitative analysis and results supported a relationship between distributed leadership and the school's capacity to improve. They concluded that distributed leadership was an important co-effect of school improvement processes. Large scale, mixed methods research by Day et al. (2007: 17) found that substantial leadership distribution was very important to a school's success in improving pupil outcomes. The findings from this study showed that distributed leadership was positively correlated with the conditions within the organization, including staff morale, which in turn impacted positively upon student behavior and student outcomes.

In their work [Leithwood et al. \(2009\)](#) and [Louis et al. \(2009\)](#) highlighted the potentially positive influence of distributed leadership practices on student outcomes. In summary, the early empirical evidence about distributed leadership and student learning was encouraging but it was clear that more work was needed to consolidate and fully explain this relationship.

The next section of this chapter moves into the more contemporary literature on distributed leadership. It draws upon scholarly work produced between 2011 and 2021 to outline the contours of the most recent research about distributed leadership. This is not a systematic review of the literature but rather a review of selected, indicative, empirical work about distributed leadership undertaken in the last decade. Initially, the methodology for the review is outlined and then, the contemporary evidence base is presented thematically.

Distributed leadership- exploring the contemporary evidence

This review of the literature looks at the latest international, contemporary evidence about distributed leadership, largely in education. As noted already, this is not a systematic review of the literature but rather, it offers an overview, based on selected, relevant, and scholarly contemporary evidence. This review focused solely on peer reviewed articles in reputable journals, that were mainly but not exclusively within the field of education. It is fully accepted therefore that there are potentially many books, book chapters and reports on this subject that are not included. The review also discounted opinion pieces, blogs, and other media.

The review focused on peer refereed, academic journals only, with the prime aim of mapping trends in the more contemporary, empirical evidence base. It is fully acknowledged that this review may have missed key work published outside journals and accepts that it has omitted scholarly work in journals written in other languages.

In this review, the data retrieval and analysis process followed the review method guidelines outlined by [Kitchenham \(2004\)](#) that also corresponds with the PRISMA ([2008](#)) methodology. In summary, the stages were:

- (1) Setting Keywords
- (2) Selecting databases
- (3) Defining search criteria
- (4) Selected articles
- (5) Analysis framework
- (6) Extracting information from the articles into the analysis framework

In terms of searching the academic literature, it was decided to use a range of databases to identify relevant articles and to cross-check these databases to ensure that all the retrieved information was accurate, and no publication was missed. EBSCOHOST was used

and the search was subsequently extended to include Web of Science for cross checking. The databases explored within EBSCO-HOST included:

- British Education Index (BEI)
- ERIC
- Education Abstracts
- Education Administration
- Academic Research Complete

The inclusion criteria for this review were:

- Source: refereed journal articles only
- Search Dates 2011–2021
- Language: English
- Search in article: title against the keywords (Distributed Leadership, Distributing Leadership, Leadership Distribution)
- Sources: only peer reviewed journals indexed in SCOPUS/ISI

The data retrieval and analysis process followed four steps, outlined in [Table 1](#) below.

- *Identification*—all studies identified in the initial results of the electronic literature search were recorded.
- *Screening*—studies that did not fully meet the inclusion criteria were excluded and duplicate results were removed from the list.
- *Eligibility*—abstract screening for each output was conducted to ensure only directly relevant and appropriate articles were selected for the next stage.
- *Inclusion*—full PDFs of the selected articles were read to ensure they remained relevant and appropriate for inclusion in the final selection.

The initial results from the search were significantly higher than the final list of articles selected. This is because many of the articles that appeared in the identification stage were irrelevant on closer inspection (e.g., many articles contained the word “distributed” but did not focus explicitly on leadership). Also, many articles were duplicates and therefore were removed. Despite a significant number of articles identified initially in the search, the rigorous filtering process for quality, direct relevance and appropriateness resulted in 44 articles being included finally in this review.

The findings from this contemporary consideration of the literature are summarized under five key themes that feature heavily and consistently in the final list of articles included. It is noticeable that while earlier research indicated that the form or patterns of distributed leadership was a significant explanation for variation in distributed leadership outcomes, the empirical work, reviewed in the next section, rarely explored the issue. The implications for future research into distributed leadership is then assessed and outlined.

Theme 1—exploring relationships

Within the contemporary literature on distributed leadership, large scale, quantitative analyses of relationships feature heavily. There are many studies that have explored the relationship between distributed leadership and some other factor or variable (e.g., academic optimism, trust). In the articles included in this overview, there are a range of relationships explored. For example, [Amels et al. \(2020\)](#) examines the relationship between teachers’ perceptions of distributed leadership and inquiry-based work in primary schools and the resulting impact on those teachers’ capacities to contribute to educational change. The results indicate a direct, positive effect of distributed leadership on teachers’ collaboration and collegiality, as well as on their motivation to contribute to educational change.

Table 1

<i>Step</i>	<i>Process</i>	<i>Number of retrieved journals (EBSCOHOST and Web of science)</i>
1. Identification	This total number of hits from the databases.	669
2. Screening	Studies that did not fully meet the inclusion criteria were excluded and duplicate results were removed from the list.	265
3. Eligibility	Abstract screening for each output was conducted to ensure only directly relevant and appropriate articles were selected for the next stage.	190
4. Inclusion	Full PDFs of the selected articles were read to ensure they remained relevant and appropriate for inclusion in the final selection.	44

Another quantitative study by [Chang \(2011\)](#) explored the relationship between distributed leadership, teachers' academic optimism and student achievement in learning. The study involved 1500 teachers and a structural equation modeling approach was applied to the data. This study found that not only did distributed leadership have a positive influence on academic optimism, but also it indirectly affected student achievement. Other quantitative studies included in this review ([Chen, 2018](#); [Hulpia et al., 2011](#); [Aldaihani, 2019](#); [Tashi, 2015](#)) focused on the relationship between distributed leadership and instructional leadership, organizational commitment, teacher professionalism, applications in high schools and teacher engagement respectively. In all but one of these studies a positive relationship was established.

Distributed leadership within the sphere of digital technologies, and the relationships therein, are the focus of some articles within this review ([Rikkerink et al., 2015](#); [Harris et al., 2013](#)) while the larger body of evidence on distributed leadership continues to explore a wide range of organizational aspects. Since 2011 there has been a burgeoning of studies, in many different countries exploring the relationship between distributed leadership and a wide range of factors or variables (e.g., [Al-Harathi and Mahdy, 2017](#); [Bellibas and Liu, 2016](#); [Coban and Atasoy, 2020](#); [Joo, 2020](#); [Zheng et al., 2019](#)). Most of these studies focus on some aspect of organizational change and largely, but not exclusively, highlight a positive relationship. Such positive relationships would be in keeping with the earlier evidence about the potential of distributed leadership to contribute to organizational change.

Conversely, a review by [Tian et al. \(2015\)](#) concluded, that the positive impact of distributed leadership on organizational change and learner outcomes remains questionable. This review, however, was limited insofar that it did not fully consider many of the key pieces of research, including some in this contemporary overview, that offer empirical confirmation of a positive relationship between distributed leadership and key aspects of organizational change.

This is not to suggest that a relationship between distributed leadership and organizational change is unequivocally established but to propose that there is sufficient empirical evidence, particularly from the contemporary research, to conclude that there is a strong possibility of a positive relationship between distributed leadership and many key organizational aspects.

Theme 2—different contexts

While the early evidence on distributed leadership tended to be Anglo-centric, with studies coming predominantly from North America and Europe, the more recent literature reveals a much broader range of countries and settings for research into distributed leadership. The contemporary literature included in this review illustrates that many more researchers from a wide range of countries and contexts are exploring distributed leadership.

Of note is the fact that there has been an uptake in research into distributed leadership in middle eastern countries. For example, [Aldaihani \(2020\)](#) examined different applications of distributed leadership in high schools in the State of Kuwait from teachers' perspectives. As a quantitative study, the study sample consisted of 1210 high schools, and it concluded that the practice of distributed leadership in Kuwaiti schools was low.

[Al-Harathi et al. \(2017\)](#) similarly examined the prevalence of distributed leadership in Egypt and Oman, using a quantitative approach. This study similarly showed that the adoption of distributed leadership practices was low, and training therefore was required. [Hashem \(2020\)](#) focuses on Jordan and is the first of the articles, in this review, to focus on the way culture affects the possibility of distributed leadership in practice. [Hashem \(2020\)](#) talks about being culturally bound by certain norms and values that make the possibility of distributed leadership practices less likely.

Other studies looked further afield and encompass countries like Turkey where [Coban and Atasoy \(2020\)](#) found a positive relationship between distributed leadership, organizational innovativeness, and teacher collaboration. [García \(2017\)](#) reports on a study into distributed leadership practices in Spain while [Hairon and Goh \(2014\)](#) offer some empirical insights into distributed leadership practices in Singapore, again largely focused on examining collaborative practices and distributed leadership. [Kangas et al. \(2015\)](#) explore distributed leadership in Finland noting that it is generally perceived to be an important part of professional development and learning.

[Harris and DeFlaminis \(2016\)](#) report on a major distributed leadership research project in the United States. The article outlines evidence about the impact of distributed leadership in schools and districts engaged in a large-scale research and development project over many years. This is one of the few longitudinal research studies of distributed leadership practice and the findings suggest a positive relationship between distributed leadership and organizational change.

This review illustrates that research is being undertaken on the topic of distributed leadership in more diverse countries and settings than was the case in the first decade of work. This is very promising and important. Yet, the contextual and cultural contours of these countries is not always given sufficient attention in the analysis or reporting of findings.

In countries where more hierarchical structures are in place and where there are high degrees of accountability, it is unsurprising that levels of distributed leadership practice are low. Conversely, where more lateral, democratic processes are in place distributed leadership is reported to be flourishing. Possibly, cultural, and contextual influences require more attention in studies going forward and it is suggested that such influences have greater explanatory power than currently explored or acknowledged.

Theme 3—instrument development

One of the pleas from researchers in the early phase of research work on distributed leadership was the need for more sophisticated instruments to capture data about distributed leadership practices. There was also a call for more large-scale mixed methods studies

of a longitudinal nature. In the articles selected for this contemporary review, only one article, [Sun and Xia \(2018\)](#) used an existing data base to explore distributed leadership and selected variables. Other studies tended to design new instruments aimed at collecting data about specific aspects of distributed leadership.

[Baloglu \(2012\)](#) focuses on the relationship between value-based leadership and distributed leadership behaviors of school principals. A simple correlational design was employed in the study involving 225 primary teachers. Data were gathered by means of a specially developed “Values Based Leadership and Distributed Leadership Inventory.” Confirmatory and exploratory factor analyses were used to define the construct validity of the scale. The findings showed that there was a 0.74 positive correlation between value based and distributed leadership and that there were four positive dimensions of distributed leadership. These four dimensions were teamwork, support, vision creating and control.

[Blitz and Modeste \(2015\)](#) outline the development and application of a Comprehensive Assessment of Leadership for Learning (CALL) which they advocate is a multi-source assessment of distributed leadership. The authors outline the use of this instrument to examine differences between teacher and leader ratings in assessing distributed leadership practice.

[Carbone et al. \(2017\)](#) describe how they used a “Distributed Leadership Benchmarking Tool” to assess how effectively distributed leadership was enabled at five Australian institutions that were implementing a collaborative teaching quality development scheme premised on bringing teams of academics, co-ordinators etc. together with the prime goal of enhancing teaching and learning. The conclusion drawn is that the benchmarking tool is useful in assessing the alignment (or otherwise) of teaching and learning.

[Mullick et al. \(2013\)](#) report on a study of teachers’ perceptions about distributed leadership for inclusive education in Bangladesh. “A Distributed Leadership Practice for Inclusive Education Scale” was developed specifically for this study. The results indicate that teachers perceived that distributed leadership practices for IE were present in primary schools in Bangladesh. The findings show that teachers’ perceptions about distributed leadership practices for inclusive education have a positive correlation with their satisfaction about the implementation of inclusive education policy.

Of those articles selected as part of this contemporary overview, only [Ersozlu and Ulusoy \(2016\)](#) adapted an existing instrument for their research purposes. The “Distributed Leadership Scale” originally developed by Davis was used to explore aspects of distributed leadership in Turkey.

While the development of new instruments to capture distributed leadership is undoubtedly a positive aspect of the more contemporary literature it is noticeable that firstly, many of these instruments capture the *perceptions* of respondents, and secondly, many of the instruments, except for [Ersozlu and Ulusoy \(2016\)](#) are *single use* only, in other words they are only reported to be used in one research study. This inevitably calls into question the extent to which a cogent knowledge base about distributed leadership can be built without the consistent, repeated use of reliable and valid instruments to collect data in different context and settings.

Theme 4—critique

The early work on distributed leadership, as acknowledged in this chapter, was not without critique. Of the selected contemporary literature within this review, there are critical pieces that follow some of the arguments made about distributed leadership in the early years of empirical enquiry. Indeed, many of the critics of the early work on distributed leadership remain vocal about the topic, a decade on.

[Gunter et al. \(2013\)](#) present distributed leadership as a study in knowledge production. They outline the development of a mapping framework to present and analyze knowledge production and distributed leadership in schools. They propose that their analysis identified the prevalence and political dominance of functional approaches and provides explanations regarding the interplay between state, public policy, and the preferred types of knowledge. [Hall \(2013\)](#) follows a similar line of argument positing that distributed leadership is located within wider structural reform of education in England as part of the New Public management movement in public service delivery. [Hall \(2013\)](#) suggests that there are “officially authorized discourses” of distributed leadership that are imposed on teachers and schools.

[Corrigan \(2013\)](#) considers the rhetoric and reality of distributed leadership, arguing that there are contrasting oppositional messages in the literature and that this calls into question the resurgence of distributed leadership. [Lumby \(2017\)](#) considers distributed leadership in the context of post bureaucratic organizations and proposes that there is little evidence that distributed leadership offers an authentic re-distribution of power. [Woods \(2016\)](#) similarly looks at authority, power, and distributed leadership, as does [Bush \(2018\)](#) who explores leadership and bureaucracy. [Crawford \(2012\)](#) returns to the issue of definitional confusion concerning distributed leadership.

Torrance challenges five generally held assumptions about distributed leadership, while [Mifsud \(2016\)](#) looks at the tension between democracy and autocracy within a distributed leadership scenario. [Or and Berkovich \(2021\)](#) look at participative decision making in schools in individualistic and collectivist cultures which speaks to the point made earlier in this chapter about the importance of acknowledging contextual influences. Such critiques remain an important dimension of the contemporary literature on distributed leadership and reinforce how, a decade later, the concept of distributed leadership is still a source of debate and discussion.

Theme 5—other disciplines

A major difference between the contemporary evidence on distributed leadership and the early work is the introduction of research that emanates from other disciplines. Within the selected review articles, a number focused on distributed leadership within other sectors. [Currie and Lockett \(2011\)](#) examine distributed leadership in practice, drawing on [Spillane's \(2006\)](#) work within the context of health and social care. [Floyd and Fung \(2015\)](#) consider the idea of distributed leadership within universities, noting that there is relatively little written on this topic. The article reports on a funded study which explored how one institution had implemented a newly conceived distributed leadership model. Their findings suggest that the challenge of distributed leadership in universities is complex on several levels that might be antithetical to the strategic direction of the institution.

[Martin et al. \(2014\)](#) describe the utility and impact of a distributed leadership model to implement a National Health Service (NHS) national quality improvement program. They report on the inclusion different groups in decision making. [Jonasson et al. \(2018\)](#) consider the implementation of distributed leadership during a hospital merger suggesting the need to understand the complex dynamics of widened and restricted leadership distribution. [Boak et al. \(2015\)](#) focus on distributed leadership, team working and service improvement in healthcare. [Nayani et al. \(2017\)](#) provide a literature review that looks at occupational safety, health leadership and the management of distributed workers.

The selected contemporary studies, highlighted here, offer only some of the insights into the challenges of distributed leadership within different settings, contexts, and structures. These studies add considerable value to the literature and provide an important comparative element that can offer researchers in the field of education new insights and perspectives.

Commentary

An assessment of the contemporary evidence base confirms that there is still much scholarly interest in the topic of distributed leadership. The sheer scale of research activity suggests that empirical interest in distributed leadership has not waned in the last decade, but conversely, has increased. This conclusion is also supported by [Gumus et al. \(2018\)](#) who found distributed leadership to be the most researched model of leadership followed by instructional leadership and transformational leadership.

It is clear, however, that most of the contemporary studies undertaken of distributed leadership within the education field still tend to be quantitative in orientation and are focused on exploring specific relationships. In contrast, qualitative studies tend to be far fewer in number and smaller in scale. Within the contemporary selected literature, there were six articles that drew upon case study data ([Ng and Ho, 2012](#); [Or et al., 2021](#); [Piot and Kelchtermans, 2015](#); [Tahir et al., 2016](#); [Tam, 2018](#); [Torrance, 2013](#)). The largest sample in these selected articles was six schools. This raises important methodological considerations and highlights the need for more broad-based, mixed method studies that can generate data with the power to generalize beyond the individual school or group of schools.

To conclude, the 64-million-dollar question is does the contemporary evidence about distributed leadership offer any new conclusions? To answer this question, requires a return to the 2008, "Seven Strong Claims about Successful School Leadership" In 2008, it made two strong claims about distributed leadership. In 2020, the authors of this seminal work revisited the claims, based on the evidence that had emerged since 2008. They concluded that a considerable body of relevant evidence had been reported since 2008, significantly increasing certainty about the validity of their claims about distributed leadership. Namely, that school leadership can have an especially positive influence on school and student outcomes when it is distributed (Claim 5) and some patterns of distribution are more effective than others (Claim 6).

A decade ago, it would have been unwise to develop bespoke leadership programs based solely on the idea of distributed leadership. The definitional, operational, and empirical platform was simply not robust enough. Now there is a clearer conceptualization of distributed leadership practice in the contemporary literature and recent empirical work has started to map relationships and sources of influence more carefully and systematically. There is also more research activity, in a diverse range of countries, addressing the outcomes and effects of distributed leadership. After two decades of empirical work on distributed leadership the research base is unquestionably richer and the understanding of the organizational influences from distributed leadership is so much deeper.

So, what has the contemporary evidence about distributed leadership yielded? While the introduction of more large-scale quantitative studies is to be welcomed, the black box of distributed leadership practice remains only partially open, there is more focused and collective empirical work to do. There are strong rays of light, however, in the form of the work around networking and professional community that show the benefits of collaborative working and distributed leadership practices. These offer strong lines of future empirical enquiry ([Harris et al., 2021](#); [Azorin et al., 2020](#)).

To conclude, future research into distributed leadership would benefit greatly from large-scale, longitudinal mixed methods studies, if the knowledge base is to improve significantly. Such empirical work should record, capture, and illuminate the way in which distributed leadership is best nurtured, incubated and supported, so that organizational transformation is possible.

An assessment of the contemporary evidence base would also suggest that more co-ordinated, collaborative, connected sets of scholarly activities could contribute greatly to a better understanding of distributed leadership. Collaborative, comparative research activity, across different contexts or settings, would ensure that the future knowledge base on distributed leadership is grounded offering the real possibility of relevant policy advice and sound professional guidance.

Introduction

The worldwide grip of distributed leadership as a favored theory of educational leadership is apparent in the academic and gray literature. Research articles flow from Africa, the Arab nations, Europe, Scandinavia and Anglophone countries. What appears evident is the one facet of distributed leadership on which the field of educational leadership can agree: that since the 1990s the theory has held a dominant role in the research and development of practice (Gumus et al., 2018). Much else is contested, including a definition, whether it is solely a heuristic lens or also a way of leading, and if its impact on learners and faculty has been positive or negative. This article adopts a critical perspective, in broad terms arguing that the theory is flawed and serves purposes other than those that are espoused. It explores some of the assertions, uncertainties, and contradictions of distributed leadership as both concept and practice. It suggests that bureaucracy is a more enduring and universal form in education and that its disparagement and disregard has been to the detriment of the field.

Critiques of distributed leadership

Distributing what?

It is not surprising that there is no agreement on a definition of distributed leadership, as it adds one opaque idea, distribution, to that of another, leadership, which itself is a highly ambiguous and contested concept. Some, such as Lakomski (2008), go so far as to consider the concept of leadership “a folk theory” and “therefore a contender for outright elimination” (p. 161). Historically, the extensive literature on theories of leadership has focused on who and what leaders are, their values, ethics, personality traits and so on, and their actions—that is, what they do, the two being interrelated. Distributed leadership has introduced into this scenario greater emphasis on leadership outcomes as unintended, emerging from the concatenation of intention and the material and social context: “leadership is the outcome both of people’s intentions (intentionality) and the complex flow of interactions in the daily life of schools (emergence)” (Woods and Roberts, 2019: 665).

Though distributed leadership reaches back at least as far as the 1950s as a concept that has much in common with shared leadership, systems leadership and other generic leadership theory, there is a more recent insistence on a theoretical distinctiveness, drawing on the developing science of cognition as a socially distributed process. Halverson (2002) uses Hutchins (1995) as a source of distributed cognition theory: “a model of the operation of a sociocultural system from which the human actor has been removed” (p. 363, original emphasis), in contrast to an earlier person-centered “model of an individual’s internal cognitive processes” (p. 249). Lakomski and Evers (2016) describe the process of socially distributed cognition as recognizing that individual intentional agency cannot account for how humans function and that “cognition, in this view, ‘leaks’ into the world, therefore is no longer bounded by skin and skull” (p. 9).

If leadership is reconceived as distributed cognition leaking from multiple individuals into the organization, it perpetuates long-term uncertainty over the concept of leadership, in particular over distinguishing leadership activity from other unintentional cognition, as potentially, everything that happens in an organization could be labeled leadership. Clarke calls this “cognitive bloat” (Clark, 2008: 80, 278). Gronn (2009: 200) translates this tendency into the context of education leadership as “a somewhat promiscuous inclination to think of virtually every initiative on the part of teachers and administrators as leadership” (p. 201).

This impulse can be illustrated by [Murphy et al. \(2009\)](#) longitudinal study of six schools in the United States over three years. This presents teachers meeting together to plan instruction more effectively as an example of distributed leadership in action. In Chinese schools, similar collaborative meetings to improve student learning are routine and are known as teacher learning or teacher research, not leadership ([Liu and Hallinger, 2018](#)). In Finland, teachers collaborate at district level to achieve curriculum reform, and this is conceived as shared sense-making, not leadership ([Pietarinen et al., 2019](#)). Collaboration by teachers to improve curriculum and learning can be traced back in the literature over half a century, variously referred to as cooperative teacher preparation, teacher development, networking, cooperative learning, sharing professional knowledge, and many other terms ([Brooks Smith, 1968](#)). Timetabling is another example of an activity undertaken by a teacher that is defined as leadership in [Murphy et al.](#)'s study on the grounds that it involves not just software manipulation but also value judgments ([Gronn, 2003](#)). The difficulty is that all educational activity involves value judgments and much of it entails working with other people. If most activities, even the most mundane, can be defined as leadership, then leadership as a distinct activity disappears.

Leadership also disappears in a second sense. [Woods and Roberts \(2019\)](#) assert that "Leadership is not reducible just to the intentions and actions of individuals" (p. 665). Such a concept of distributed leadership as an emerging, spontaneous, fluid and dispersed activity offers a solipsistic vision in which the embodied human leader disappears behind the disembodied concept of leadership. In using [Hutchins' \(1995\)](#) construction of cognition as a sociocultural system separate from human actors, [Halverson \(2002\)](#) acknowledges as much. A critical perspective insists, to the contrary, that educational organizations' service to learners is embodied, dependent on the socially (un)just intentions and actions of individuals, and that the impact of action relates to the differential power that they hold. Such power may draw on the authority of a particular role but, equally, may relate to knowledge, access to resources or networks, charisma, or a host of other factors. The critical factor in supporting leaders, for practical purposes, is that individual human beings use conscious intention. The guidance of practice engages the leader's intention and, in any attempt to bring about change, the consciousness of power is crucial.

Power and distributed leadership

Power is essentially the capacity to influence or direct others to act in a way that the powerholder wishes ([Lumby, 2019a](#)). This straightforward definition overlies a number of complex and contested theories on how such capacity is acquired and implemented. Direct orders may be used but, equally, indirect strategies may shape the playing field, and even the mindset of the players so that their actions are influenced, circumscribed, or shaped without them necessarily being aware of it ([Lukes, 1974](#)).

Competing ontologies underlie the research on leadership in education and, consequently, our concepts of power and organizations. On one hand are concepts in which faculty can be trusted to use their professional knowledge in the interests of learners. Here, cooperation functions effectively, based on "educational traditions and changes infused by different visions—those that prioritize collaboration, democratic values and humanistic aims" ([Woods and Roberts, 2019: 663](#)) that are embodied in practice; that is, "a shift away from a leadership paradigm based on power and control" ([Halpin, 2003: 85](#)). On the other hand, a much less promulgated vision sees leaders, teachers and organizations quite differently. Research from the 1980s ([Hoyle, 1982](#)) to more recently ([Brosky, 2011](#); [Samier, 2014](#); [Lochmiller and Pawlicki, 2018](#)) has shown that educators are perceived to work for what is best for their learners only in part ([Piot and Kelchtermans, 2016](#)). They also pursue individual and or partisan goals by means of relationships, forming coalitions and engaging in conflict. What is best for learners is contested, and action is arrived at through the temporary resolution of the ongoing competition between these interests. This view presents organizations as places where, regardless of which structural changes are made, hierarchies and coalitions emerge ([Courpasson and Clegg, 2006](#)).

Power in the field of education is generally viewed negatively, as compulsion or manipulation, both of which are assumed to undermine professionalism. Professionalism "gives central stage to and trusts the professional judgment of teacher educators to do what they deem is good, appropriate, or best" ([Vanassche et al., 2019: 485](#)). Faculty's freedom to do as they wish is argued to be essential to the effectiveness of education and the self-identity of educators, justified by their context-specific knowledge and skills. An erosion of professionalism has been strongly linked to analyses of managerialism since the 1990s and embodies resistance to the perceived growing power of senior authority figures. Distributed leadership uses the same argument as professionalism, linking greater faculty autonomy to effectiveness by means of lessening power differentials and opening up leadership.

A vision that rejects oligarchy and offers greater freedom and equity, as befits the professionalism of educators, is an attractive prospect for self-identity and, perhaps because of this, is widely evident in the literature on educational leadership in the last three decades. Micropolitically based research and analyses are less frequent: the view of educators pursuing self-interest as well as learners' interests is far less comfortable. However, many argue this it is neither a negative nor a cynical picture but simply a reflection of the reality of day-to-day life in schools, colleges, and universities ([Bolden, 2004](#); [Brosky, 2011](#)). It is perhaps a more clear-sighted assessment that both at national and organizational level: "Much of the time, education is not about what is best for children; it is about the adult issues of power and control" ([Owen, 2006: 103](#)).

Schools, colleges and universities are unlikely to be staffed by faculty who completely put aside their self-interest and engage in no conflict or micropolitical strategies. Nor are they devoid of those who wish to do the best for learners for much of the time and sincerely pursue what they deem to be a path of integrity. Most faculty are neither angels nor demons but a complex mix of self-awareness and self-deception, and who both collaborate and oppose. The absolutes to be relied upon are that power will be in play and that trust in faculty will inevitably be circumscribed by a realistic vision of human capacity rather than an idealization of professionalism.

Such a position can be traced in the critical literature on professionalism, which recognizes that educators' power is typically invisible. Where it is discernible, power is presented as necessary to the interests of the learner (Osgood, 2006). The classic features of professionalism, which include the acquisition and deployment of a specialized set of skills and vocabulary to provide appropriate ethical service to the client, shape it as an "apolitical and common-sense construct" (p. 5). Many commentators suggest that this "appearance of neutrality" (Bourdieu and Wacquant, 1992: 242) disguises a struggle for control, where the discourse is a tool for the acquisition of power. Its purpose as a means for the professional to gain greater autonomy and control must be hidden, even from the professionals in question, as pursuing power contradicts a self-identity based on devotion to service (Noordegraaf and Schinkel, 2011).

Until the 1990s, the functional literature on professionalism largely served as a means to resist perceived attempts by the state to control educators (Dillabough, 1999). From the 1990s onwards, the concept of distributed leadership has arguably taken over as the major discourse proposing greater autonomy for educators to lead in the interests of the learner (Leithwood et al., 2019). Just as the literature on professionalism insisted that improved service to the learner was the underlying justification for faculty's preference for autonomy, so has distributed leadership emphasized the learner as the primary beneficiary. For example, Leithwood et al. (2019) insist that distributed leadership's positive impact on learner outcomes has been proven empirically and those who question it are mistaken. Consequently, from professionalism to distributed leadership, an unbroken tradition can be discerned in the education leadership literature. Both discourses are used essentially to fight for greater faculty autonomy. In both cases, improving learning is the major justification and the power that shapes which faculty gain greater autonomy or otherwise is largely bleached out, as is faculty's resistance to the power of, or the control by those in authority roles and the state.

Distributed leadership has been frequently critiqued for not translating ideals about power into specific actions, structures, and processes (Hatcher, 2005; Flessa, 2009). For example, Murphy et al. (2009) suggest that "distributed leadership must grow from the soil of changed organizational and professional norms and be actively nurtured by administrative leaders in a variety of ways" (p. 189): these "ways" are not explained. Flessa (2009) points out that, while Spillane and Diamond (2007) instruct us to pay close attention to interaction, not just action, they neither explicitly engage with micropolitical understandings of how human beings interact, nor draw out how we are to interpret interactions and respond in terms of improving learners' experience. Woods and Roberts (2018: 677) provide a list of principles to support the development of collaborative leadership. Their suggestions, such as "a partnership between schools and external agencies" or "opportunities for open discussion", ignore the likely power plays inherent in such partnerships and communications (Griffiths et al., 2009). A detailed analysis of the literature on distributed leadership reveals either a general pursuit of idealized change, such as unspecified transformations of culture or structure, or, when more explicit, actions that for decades have been part of leaders' repertoire and fail to distinguish distributed leadership as different from what went before.

Osgood (2006) argues that communities locate themselves in relation to discourses that "reflect the socially sanctioned dominance of certain ideologies and subjugation of others" (Sinclair, 1996: 232) and that "alternative counter-discourses become pathologized and marginalized" (p. 6). This is the case with distributed leadership, which has largely supplanted other theories of leadership. Following Foucault's insistence that we consider alternative perspectives, the questions then are: If the guidance based on distributed leadership as a concept lacks engagement with the reality of day-to-day life in educational organizations, are any other theories more compelling? What theory or theories best support fallible human beings, working in contexts where ideals and micropolitical interests coexist? It might be a helpful exercise to consider the most pathologized theory of all, bureaucracy.

Bureaucracy

The features of bureaucracy as outlined by Weber (1947) are widely known: the appointment and reward of faculty on merit related to their education, training and experience; labor demarcated by role and expertise; a hierarchy within which each is subject to the instruction of superiors through agreed rules and procedures; and security of tenure. Bureaucracy is "founded on authority, that is, the belief in a legitimate, rational-legal political order" (Olsen, 2005: 2). Both in societal discourse and in education, the term has come to be connected with, at best, negative and restricting structures and processes and, at worst, malign intentions that dehumanize and undermine individual agency (Courpasson and Clegg, 2006; Fitzgerald, 2009). However, its origins relate strongly to values of justice and equality. Just as distributed leadership now claims to be a response to the changing context of society and organizations, and specifically increased complexity, so Weber's (1989a) conception of bureaucracy was in response to "the general growth in those demands on the administration, which result from the increasing complexity of civilization" (p. 348), and a shift from nineteenth-century models of leadership to one that he saw as more rational and so potentially more effective.

As initially conceived, bureaucracy offered an alternative to the untrammelled power of oligarchy, with its historic baggage of nepotism, simony, corruption and other forms of exclusion, such as "race" (Weber, 1989b). The distinctive, rule-based approach that is currently deplored by many was an attempt by Weber (1947) to conceive a method not to inhibit all human initiative but to prevent illegitimate behavior, thus protecting the individual and, by this means, to secure effective organizational functioning (Kallinikos, 2004). Just as many believe that society moves forward by offering all citizens the protection of being subject to the rule of law, so bureaucracy subordinates all members of an organization to the same rules, thereby attempting to circumvent arbitrary or self-seeking action by those with most power.

In its vision of greater equality and more open access to leadership, distributed leadership is based on a positive view of human nature and capacities. Similarly, bureaucracy implies a view of human nature, but it is a less optimistic view. It assumes that human

beings are not always fitted for particular leadership roles, nor will they always put the interests of the organization first. Selection and boundaries are required. Bureaucracy assumes that faculty will want a structure that promotes their career, rules about salary, security of tenure, and access to opportunities that are based on rational decisions: the “‘objective’ execution of business in this context means execution which has ‘no regard for persons’ and which follows calculable rules” (Weber, 1989a: 351).

Weber’s hope was that a bureaucratic organization might go some way toward eliminating the sometimes overt and sometimes subtle or covert means by which some people rise more than others in terms of status, salary and access to challenging work, to the detriment of those whom the organization serves. However, the notion that an organization with classic bureaucratic features would banish inappropriate behavior is as much an ideal type as distributed leadership. Weber (1947) suggested that sociologists need to conceive of pure forms of organization in order to be able to make distinctions and evaluate implications; however, “this ideal *pure* form, is perhaps as little likely to be found in the real world as is a physical reaction, calculated on the assumption of an absolute vacuum” (Weber, 1989b: 23, original emphasis). He reflected on the potential of bureaucratic organizations to support ethical and effective functioning that opened up opportunities to individuals based on training, experience and equality before the rules, yet he was also aware of the possibility that application of the model could tip into a rigid and dysfunctional application of systems. From its inception, the concept of bureaucracy accepted the inevitability that human beings would use organizational forms of leadership both to achieve positive outcomes and to subvert them with negative consequences.

Some critics of distributed leadership have similarly conceived of negative outcomes from distributed leadership in practice (Bolden et al., 2009; Hatcher, 2005), but many more have promoted it on the basis that deliberate encouragement of many into leadership roles and fluid self-selection of leaders represents a liberation that leads to greater organizational effectiveness. The potential for distributed leadership to deepen exclusion, and thereby reduce effectiveness, is less evident in the literature. The formal or informal appointment or the spontaneous emergence of a leader may be predicated not just on an individual’s choice but on the willingness of others to accept him or her as a leader. Consequently, stereotypical prototypes of what a leader looks like serve to shape the willingness to support. These may relate as much to unjustified prejudice as to the individual’s expertise. The flows into and out of leadership according to organizational need, which is suggested by some to be an identifier of distributed leadership, depict an organization as apolitical, free from sexism, racism, and other forms of prejudice. Simultaneously, numerous studies of distributed leadership in action repeatedly show both control over entry into leadership by those in senior positions and the exclusion of some individuals for reasons other than capability (Hairon et al., 2014; Murphy et al., 2009).

Qualifiers such as “bounded empowerment” (Bouwman et al., 2019: 568) or “pragmatic schools” (Hairon et al., 2014: 370) have emerged to limit the earlier optimistic explorations of distributed leadership. The latter study suggests that distributed leadership is useful in Singapore schools, while also making it clear that faculty are uncomfortable with the notion and do not wish to expend time on leadership which they see as the province of those appointed to such roles: “they do not wish to spend time for the self-organization work needed” (p. 379). This quotation raises the issue of the cultural inappropriateness of distributed leadership in parts of the world that do not prize a reduction in power distance to the same extent that is evident in the West, where the concept of distributed leadership evolved.

Sustaining the weakness of the field

The research on distributed leadership perpetuates several weaknesses in the field of education leadership: poor historical awareness; side-lining of inconvenient alternative perspectives; unacknowledged methodological limitations; cultural colonialism through global promotion of a concept based on Western values; and marginalization of the issue of exclusion.

Poor historical awareness

An example of poor historical awareness is the excoriation of bureaucracy and the presentation of distributed leadership as overturning what are characterized as the nineteenth-century values and structures that inhibit leadership by the many (Murphy et al., 2009; Day et al., 2010). Such assertions are based on “oversimplified and stylized images of the bureaucratic form ... marked by an astonishingly naïve functionalism devoid of any historical awareness” (Kallinikos, 2004: 2). The initial purpose of bureaucratic forms, to create more egalitarian, just, and effective organizations, is lost and replaced by a caricature that presents only its potential disadvantages, which Weber (1947) fully anticipated and acknowledged, and none of its advantages.

Theoretical evangelism

Much of distributed leadership research’s blindness to alternative perspectives can be illustrated by reference to bureaucracy. Some assert that distributed leadership is evident in all educational organizations, given that spontaneous leadership will emerge in a group of people whatever its intentions, structure, or culture (Gronn, 2016). Woods and Roberts (2013) insist that “leadership is a distributed phenomenon”; however, there is at least as much evidence that education embodies bureaucracy, given its widely evident framework of rules, standards and processes, sometimes state-mandated, matching the features of bureaucracy. The persistence of evidence showing that in education the dominant form is a formal hierarchy (Earley et al., 2012) is played down by assertions that, within a distributed leadership system, formal leaders are still necessary and that hierarchy runs alongside heterarchy (Zala-Mezö et al., 2019). What a hierarchy brings positively to leadership is either underexplored or categorized as

a component of distributed leadership. A key characteristic of bureaucracy, the allocation of roles to those with relevant expertise, is explained exclusively as a facet of distributed leadership: for example, “patterns of leadership distribution tend to be based on patterns of expertise” in “authentic distributed leadership” (Leithwood et al., 2019: 10) rather than being analyzed as a defining characteristic of bureaucracy. There is a tendency to characterize factors as illustrating or providing evidence of the presence of distributed leadership even though they could just as well be evidence of alternative forms of leadership using other theoretical frameworks.

Compare research in educational leadership with that in generic leadership and a different breadth becomes apparent. Bureaucracy rarely appears in educational leadership research except as something to be avoided, replaced, or deplored (Lumby, 2019b). By contrast, generic leadership research has engaged with challenging and developing bureaucracy, evolving new concepts such as representative bureaucracy (Kemp et al., 2019) and hybrid adaptive bureaucracy (Zhi and Pearson, 2017), just two illustrative examples of many attempts to evolve hybrid and alternative models in public services (Fotaki and Jingit, 2018). The narrow focus on distributed leadership in educational leadership research has deprived the field of necessary knowledge and insights into the bureaucratic form that is, to some degree, evident in all educational organizations.

Insufficient interrogation of research methodology

The primary justification for the introduction of distributed leadership as a practice is that it will improve learning. The literature on distributed leadership asserts its connection to improved student outcomes. For example, Harris (2008: 3) claims that “Distributed leadership is a common denominator of highly effective organizations across different sectors”. Many researchers make similar claims (Timperley, 2008; Day et al., 2010). Research has focused increasingly on identifying the connection definitively. For instance, Heck and Hallinger (2010) conducted a large-scale, longitudinal study and concluded that “the evidence therefore suggests that change in distributed leadership can be empirically linked to change in school improvement capacity and subsequent growth in student learning” (p. 881). Such claims continue (Supovitz et al., 2019).

The extent to which relevant research is considered trustworthy determines whether a connection is accepted between distributed leadership and improved student outcomes. Multiple issues have been raised. First is the widely expressed difficulty in reaching a clear definition of distributed leadership that is adequate for translation into distinctive and reliable research factors across differing contexts. However, increasingly, commentators insist that distributed leadership takes various forms (Bolden et al., 2009; Robinson, 2009; Leithwood et al., 2019), leading Robinson to suggest that the appropriate question is not whether there is a connection between distributed leadership and improved student outcomes but “What are the relative impacts of particular types of distributed leadership practice?” (p. 238). The evidence about any such connection would need to be sorted by its relation to the particular form of distributed leadership, were there a sufficiently clear definition of each and a way to identify which was under scrutiny. The evidence’s relationship to the culture of the research location would also need to be assessed. A form may appear positive in, say, Hong Kong but not South Africa. Only then could the data be interrogated to see if the evidence is sufficiently robust. Often these conditions have not been met, and some researchers have acknowledged weaknesses in the research (Heck and Hallinger, 2010) or suggested that, while the connection is unproven it remains “intuitively attractive” (Hairon and Goh, 2015: 694).

A further problem is that if the argument is accepted that leadership is always distributed (Woods and Roberts, 2013), then a counterfactual is impossible: it is not feasible to eliminate distributed leadership from a control group school(s) or parts of a school in order to assess its impact. Despite assertions that those who question the evidence of improved student outcomes have either consulted insufficient literature or misunderstood it (Harris and DeFlaminis, 2016; Leithwood et al., 2019), many research issues remain unresolved: inadequate definition (Lakowski, 2008); reliance on self-reported data, whether through interview or survey; insufficient attention to the impact of the researcher’s presence, understood by some as the “Hawthorne effect” (Stand, 2000); the difficulty in establishing a control group and researcher bias, given the extent of investment by both national policy and research systems in this form of leadership (Lumby, 2019b). All conceptual frameworks bias the results to some degree, but it would be useful if those researching distributed leadership could interrogate the weaknesses in this research more fully.

Colonization by research theories

Such interrogation is less likely in a study whose researchers and the faculty at the research site are proponents of distributed leadership, leading to potential bias in the study’s self-reported data and analysis. In particular, the cultural fit of distributed leadership appears at times to be set aside to demonstrate its presence, however it is defined by a study, even when its data suggest that this is doubtful. For example, Hairon et al.’s. (2014) data analysis shows leaders’ “reluctance to relinquish key operational decisions to subordinates or only encourage faculty to make decisions within their work scope”, relating this to Singapore’s culture. Yet no question is raised about whether the data indicate the presence of distributed leadership or, instead, another kind of leadership. In many parts of the world, propelled by the support of many researchers and the OECD (2008), in the field of education leadership the square pegs of distributed leadership are hammered into cultural round holes. This perpetuates the tradition of colonization by theory; that is, the eager export and adoption of theories originating in Anglophone countries by those whose culture and values may be quite different (Normore and Collard, 2007).

Blindness to exclusion

Education leadership research is generally bifurcated. Much includes, at best, a token reference to the forms of prejudice embedded in education, such as sexism and racism. Much less is critical research giving centrality to issues of inequity and exclusion among both faculty and learners. Distributed leadership generally falls into the first category.

One justification of distributed leadership is that it opens up leadership to more people; however, if opportunities were indeed being opened up, one would expect to see more people with stigmatized characteristics using informal opportunities as a lever to access formal paid roles or, at least, generally experiencing less exclusion. The literature from many parts of the world supports no such change. Those groups of people who are underrepresented in leadership continue to be so, and in some cases their experience in the workplace blights their professional life (Bush, 2019; Ho, 2015; deLeon and Cryss Brunner, 2012). Distributed leadership appears to have raised expectations for greater leadership opportunities that are not always fulfilled. For example, Holloway et al. (2018) examined one form of distributed leadership in the United States and found that teachers' "expectations were unrealistic" (p. 538). They concluded "that prescribed, incentive-driven forms of distributed leadership can place teacher leaders in precarious positions that demand more of their time, while limiting their capacities to participate in the leadership practices they deem most valuable" (Holloway et al., 2018). Far from improving their opportunities, distributed leadership had, in some cases, been a mechanism to extract more work from teachers. Although some critical literature attempts to point out that people's participation in the putative greater opportunities persists in being shaped by power structures (Lumby, 2013) or social and professional capitals (Woods, 2016), a great many articles set this understanding aside.

A second justification for distributed leadership is that it offers a lens through which to understand the totality of leadership. If this promise were met, it would be a valuable step forward. One might expect to see a range of research encompassing political and critical as well as functional perspectives, exploring in detail how people access leadership or not, their experiences while leading, and how these impact on learners. Instead, there are characteristically surveys, where teachers self-report using a range of factors, some of which could be elements from other forms of leadership, correlated to learner outcomes. Distributed leadership does not appear to have contributed to a fuller picture of leadership to lead us to understand the complex mesh of interactions that enable some, but not others, to take on leadership roles.

The future of leadership theory

Just as there are debates on whether schools reflect or lead society, so one might question whether theories of leadership improve the experience and outcomes of faculty and learners' or contribute to the mesh of phenomena that construct the current inequalities and failings. The very least one might expect of research in this field is self-interrogation, a critical awareness of the potentialities of any form of leadership to resist or sustain unequal systems; however, rather than rigorous self-interrogation, distributed leadership has proved a ready tool for smoothing over the complexities of leadership. Spillane and Diamond (2007) point out the irony whereby the very vagueness of its meaning contributes to distributed leadership's popularity. It has proved a useful label to attach to various leadership activities, carrying with it its positive spin of admirable intentions. Despite claims by some that it widens leadership opportunities, there is evidence that it extracts more work, so is part of the work-intensification project of globalization, and that it sidesteps any explicit engagement in creating opportunities for those groups most likely to be excluded. In an era of populism, the advent of highly visible leaders who flout the traditional public-sector values of honesty, transparency and inclusion demonstrates the dangers of leadership that has insufficient safeguards, balances, and boundaries. The field of education leadership has focused on distributed leadership and set aside the development of forms of leadership that may offer greater protections, such as bureaucracy.

The problem then, is not distributed leadership itself, whose inception was intended to interrogate the complexity of leadership more fully, but rather how it has become a mechanism for the mainstream field of educational leadership to persist in largely ignoring the political and discriminatory aspects of education organizations. This is not to argue that its adoption, in its very many configurations, has not had positive impacts: the Hawthorne effect alone would guarantee this. Nor is it to argue that other forms of leadership will not have their disadvantages as well as advantages. Rather, a critical perspective would demand a more rigorous exploration into distributed leadership's potential negatives by mainstream research instead of banishment to its margins. A deeper engagement with concepts of power and organization is needed, recognizing that, as Ahlberg and Nightingale (2018) argue, "acts of resistance to subjection ... simultaneously confirm and reiterate social hierarchies and discriminatory norms" (p. 385).

Distributed leadership as practice has sought, to use Judith Butler's (1990) term, to "trouble" the prevailing relations in the hierarchies of education organizations without reference to the long-acknowledged paradox whereby resistance both diminishes and heightens existing power relations. Often this is achieved by using three-dimensional power where a field of action serves to manipulate individuals to internalize beliefs that perpetuate the power differentials while they imagine that they are doing the opposite (Foucault, 1974). Distributed leadership has operated in this way. Alongside its apparent role in opening up opportunities and redressing power imbalance, distributed leadership has been a vehicle to perpetuate weaknesses in the field of education leadership research and practice, and so it has served leaders less well than is claimed by many.

Introduction

Leadership has long been acknowledged as a key factor in school effectiveness, with leadership being only second to teaching in its impact on pupil outcomes. Many studies have shown leadership to have a significant albeit modest and largely indirect effect on attainment. School leadership typically account for approximately a fifth to a quarter of school level variance in pupil attainment, once intake and pupil background have been factored in the indirect effect of leadership is even greater, as it influences school climate, disciplinary climate, teaching quality, curriculum, relations and therefore almost everything that happens in the school as an organization. Furthermore, the impact of school leadership is greatest in schools serving the most disadvantaged (Leithwood et al., 2004, 2006; Huber and Muijs, 2010; Robinson and Gray, 2019). It is therefore not surprising to find that large-scale international studies have also looked at this factor as an explanatory factor in pupil attainment (as in PISA), and as a factor of importance in and of itself (as in TALIS).

The broad conclusions on the importance and impact of leadership drawn in the literature on leadership and school effectiveness do however mask some differences in how leadership has been conceptualized. Over time, a consensus view has emerged, though, as well will see below, this is now being contested.

In this chapter we will therefore look at how leadership is conceptualized in LISA's, such as TALIS, TIMMSS/PIRLS and PISA, what the key findings from these studies are, and how the current conceptualization and use of leadership in the leadership corresponds with the newest insights on leadership in education.

In this review I will disregard studies that have simply used international study rankings to choose countries high (or low) and then separately study these on leadership and other factors, due to the methodological weaknesses of such designs in that they do not take sufficient account of the variety of cultural and other differences between countries, and therefore tend to more resemble a fishing expedition than scientific research.

Defining leadership

While long considered a key factor in organizational performance, leadership can be a somewhat nebulous and ill-defined construct. For some, leadership is essentially defined by organizational role, thus in an educational context equating leadership with the person(s) of the leader, typically the principal and the senior leadership team in the school. Leadership is then essentially what the leader(s) does (do). A second research tradition focuses more on the characteristics of the person in the role. Here we see an evolution from charismatic views of leadership, whereby innate traits are studied, to an emphasis on behavior and beliefs of leaders, leading to transformational theories of leadership. In education, these have often been supplemented or supplanted by instructional leadership, about which we will write more below. However, prevailing views tend to see leadership as much as a characteristic of the organization as of individuals, with distributed leadership models having become popular in education, not least in the form of teacher leadership. Increasingly, as the role of schools as part of a wider social and educational system have increasingly been acknowledged, system leadership has become to be seen as part of the school leader job description (Muijs, 2011).

Recently, there has been growing critique of these prevailing models of educational leadership, which are seen as too generic, and insufficiently focused on knowledge. In this alternative perspective, contextual knowledge about education, curriculum, didactics and pedagogy should form the basis for effective school leadership (Lock and Rees, 2020). This view has started to influence leadership development in a number of places, notably England, where it has helped inform the new national professional leadership qualifications (Jerrim and Sims, 2019).

This new perspective sees school leadership as:

- Complex. This recognizes the complexity of the role, and therefore that much of the work of leaders is solving complex problems while realizing their own limitations as they engage in this work.
- Domain-specific. Leadership is much more about specific knowledge in a particular field than generic typologies such as distributed or transformational leadership. It therefore requires in-depth knowledge of education in areas such as pedagogy and curriculum

- Knowledge-centric. Rather than a set of more-or-less generic skills, leadership is built on in-depth knowledge
- Problem-focused: key to leadership is the ability to deal with persistent (complex) problems
- Context-specific. Leadership start with understanding the specific school context.

In light of these differences, it is important to understand how leadership is defined in the major international studies.

TALIS, which looks at leadership most comprehensively of the international studies, provides a short theoretical summary in their conceptual framework for the 2018 survey of teachers and school leaders. While no overall definition of leadership is given, the framework draws on Day et al. (2016) summary of characteristics of effective school leadership. TALIS puts a lot of emphasis on instructional leadership, defined as “supporting and developing high-quality instructional practices, developing and implementing policies that support student achievement, developing learning communities, providing feedback on instruction, modeling effective instruction, and supporting the use of assessment data” (Ainley and Carstens, 2018). TALIS also points to a growth in the importance and attention paid to system leadership in the field since the previous survey. The third pillar of the framework is distributed leadership, again seen as an area that has received increasing prominence in the period before development of TALIS 2018. In the study itself TALIS looks at five dimensions through its questionnaires:

1. Characteristics of school leaders, e.g. qualifications, recruitment;
2. What school leaders do: role, function and work of the principal, instructional leadership, terms and conditions, workload, hours, autonomy, function, and actions;
3. Distributed leadership and teacher leadership;
4. Principal job satisfaction; and
5. System leadership and leadership in networks of schools.

PISA included items on school management/leadership in the school context survey up to 2015. In the subsequent two administrations these items were no longer included. The items in the earlier editions reflect instructional and distributed leadership models, as well as an emphasis on governance models (who at which level from national government to teacher is responsible for what) (OECD, 2017, 2019).

The latest iterations of TIMSS/PIRRLS focus primarily on principal qualifications and experience, though previously a “leadership activities scale” was included in the school questionnaire. In this scale principals were asked how much time they spent on a range of leadership activities, reflecting one of four aspects of school leadership: (1) school vision, (2) safe and orderly environment, (3) faculty trust, and (4) professional development. Principals were asked to respond using a rating scale with three categories (1 = No time, 2 = Some time, 3 = A lot of time) IEA (Mullins et al., 2012; Reynolds et al., 2023).

The LISA frameworks therefore reflect a view of leadership both as a role, with a clear focus on school principals, their background, their characteristics and what they do, supplemented by some attention (especially in TALIS and earlier iterations of PISA up to 2015) on instructional distributed leadership. These frameworks tend toward the traditional definitions of leadership around key concepts such as distributed or instructional leadership, rather than toward the new thinking that stresses knowledge, complexity and specificity, and primarily focus on the principal on the one hand and teacher input on the other, with little attention to intermediary levels of leadership in schools (such as middle leaders).

It is notable that the attention paid to leadership has diminished in recent versions of both PISA and TIMSS/PIRRLS. We will discuss more later in this chapter.

What does leadership look like?

The main evidence on what school leadership looks like internationally comes from the TALIS studies.

A range of analyses of the TALIS 2013 and 2018 datasets have been undertaken, looking at different aspects of leadership, such as instructional and distributed leadership behaviors, based on either ratings from the principal scales or from the teacher survey (e.g. teacher rating of principal instructional leadership and distributed leadership, Xia and O’Shea, 2022).

TALIS generally reports quite high levels of instructional leadership across countries, while the picture on distributed leadership is more mixed.

In terms of instructional leadership, almost 60% of principals across TALIS (2018) participating countries claim to be using direct forms of instructional leadership, such as collaborating with teachers on school discipline, leading professional development, observing teachers and providing feedback. An even greater proportion of principals (typically over two-thirds of respondents) were involved in activities related to indirect instructional leadership, such as actions to ensure that teachers feel responsible for their students’ learning outcomes, actions to ensure that teachers take responsibility for improving their teaching skills, and actions to support co-operation among teachers to develop new teaching practices (OECD, 2021b).

Looking then at distributed leadership we find that involvement of teachers in school management and decision making is variable, and quite limited in many schools and countries (OECD, 2021b). Overall, according to responses to the principal survey around 42% of schools have high levels of teacher participation in decision making. There are, however, clear differences between questions asked (e.g. when principals are asked whether teachers are involved in decision-making almost all say they are, when asked more specifically about teacher membership of the senior management team the proportion in some countries is as low as 25%). There are also large differences between teachers’ and principals’ responses to questions on their perceived influence and control, with the former, unsurprisingly, reporting much lower levels than the latter.

Principals don't collaborate with other principals and school leaders all that often (just over a third), suggesting that the system leadership elements of the role are less developed (OECD, 2021b).

These results from TALIS factors remain largely unchanged compared to TALIS 2013.

Of course, a key question is the extent to which the constructs used in TALIS are in fact invariant across countries. This is not entirely clear using the Rasch model to analyze the leadership activities scale from PIRLS and TIMSS, Zhang and Wind (2019) compared Hong Kong SAR, Chinese Taipei, the United States, and Canada, finding that perceived ordering of activities across countries differed to some extent. In particular, the two East-Asian countries differed significantly from the two North American countries on perceptions in two main areas. The main differences were on items relating to regulating student behavior, on which principals in the North American countries spent significantly more time, and items on visiting other schools and conferences, which was more common among principals in the East Asian countries. Differences in most of the other items were limited, however. Differences in factor structure between Germany and Chinese Taipei were found in a study comparing TIMSS (2011) data. In Germany, the researcher extracted four leadership styles using CFA and MLSEM: distributed leadership style (26%), the integrated instructional and transformational leadership style (27%), the transformational leadership style (7%), and the instructional leadership style (40%). In Chinese Taipei only two styles were extracted: the integrated instructional and transformational leadership style (36%), and the mixed integrated instructional and distributed leadership style (64%) (Chen, 2018). However, using the same data the research team found that the basic dimensions of vision/goal (S1), management (S2), maintaining school climate (S3), and principal leadership did fit the data in both countries (Chen et al., 2020). Looking at PISA 2015 data, Gao et al. (2018) claim factorial invariance for the construct of principal decision making across China and the US. However, this was only achieved by the statistically dubious practice of removing the constraints with the largest modification indices.

Not only are there cross-country differences in how leadership is conceptualized and understood, but there is also the methodological issue of differences in self-report measures from principals and teachers. This is evident in TALIS, for example, where principals' and teachers' views on distributed leadership in their schools differ substantially (with principals generally perceiving greater levels of DL than teachers) (Printy and Liu, 2021), and where teachers see instructional leadership as a unidimensional construct, whereas it is multi-faceted among principals (setting goals, professional development, and supervision of instruction) (Urick and Bowers, 2019).

Country differences are not always apparent, however. Analyzing TALIS 2018 data, Veletic and Olsen (2021) used cluster analysis to identify five clusters of practice relating to leadership for learning. They found that these clusters differ substantially more between schools within countries than between countries, and that country differences are unrelated to geographical/cultural groupings of countries.

Leadership and attainment

As mentioned in the introduction, the consensus among researchers into educational leadership is that there is a significant, albeit mainly indirect, impact of leadership on pupil attainment. The LISA studies paint a far less clear picture of this relationship, however.

Analysis of the 2018 TALIS-PISA link dataset does indeed show an indirect effect of principal leadership on pupil attainment. The findings also point to a number of key factors leaders need to focus on to enhance pupil attainment, especially ensuring a disciplined school climate focused on achievement, and supporting teachers by maximizing the time they can spend on teaching and learning and minimizing unnecessary workload and stress (OECD, 2021a,b,c).

An analysis of TALIS data for the English education ministry showed significant differences between countries in requirements for training and development of principal, salary, teaching requirements and available CPD. There was however, little evidence of a relationship between these factors and student outcomes. There was some limited evidence that principals in high performing countries, with principals in selected high performing countries valuing instructional and distributed leadership, but the methodology (selecting countries) makes such conclusions highly tentative (Greatbatch and Tate, 2018).

As well as the 2018 PISA-TALIS link dataset, there are also a range of analyses from PISA 2015 (in which the school questionnaire contained a number of scales and items relating to principal leadership). One study, for example, looked at four dimensions of leadership from the school questionnaire and correlated these to outcomes in science, maths and English. They found a positive relationship between instructional leadership and outcomes, while support for professional development was negatively related to outcomes. Goal setting and distributed leadership were not significant, and the overall relationship with leadership was negative (Wu et al., 2019). On the other hand, in a study using data from the teacher questionnaire, Wu et al. (2020) did find a significant relationship between principal leadership and attainment in science in the US 2015 PISA database. Using the German data from PISA 2015, a positive relationship was found between instructional leadership and exchange of materials between teachers, but this in turn was negatively related to attainment (Mora-Ruano et al., 2021). Using TIMSS 2011 data comparing Germany and Chinese Taipei, Chen et al. (2020) found that principal leadership in general had a negative relationship with students' mathematics achievement in Germany, but had a non-significant relationship in Chinese Taipei. The researchers also looked at the relationship between each category of principal leadership and students' mathematics achievement in both countries. The results showed a stronger focus on setting vision/goal and on maintaining school climate was negatively related to students' mathematics achievement in Germany, while a stronger focus on school management was positively related to achievement. In Chinese Taipei

maintaining school climate was positively associated with achievement, and school management negatively. Setting vision/goal was unrelated to students' mathematics achievement.

Using PISA 2009 data for a comparative study of Korea, Mexico and the US, [Shin et al. \(2013\)](#) also found very mixed results. Principals' perceptions of their instructional leadership were positively related to PISA scores in Korea but negatively in Mexico and the United States. Similarly, principals' perceptions of their leadership of teachers showed a positive relationship with PISA scores in Mexico but was negative in the other two countries; and principals' perceptions of their leadership for professional development were negatively correlated in Korea but positively in Mexico and the United States.

Looking at distributed leadership with PISA 2015 data, [Luschei and Jeong \(2021\)](#) report that increases in teacher decision-making responsibilities were positively related to student achievement in math, reading, and science. This was not the case for any other aspect of principal leadership, however.

The final set of studies on leadership and attainment use TIMSS and PIRLS data. Again, these tend to be from earlier studies as the emphasis on leadership has decreased in recent administrations.

Comparing the US and Flanders using TIMSS (2011) data, [Urlick et al. \(2022\)](#) found that principal instructional leadership was related to opportunity to learn in both countries, but that the relationship was stronger in Flanders. The pathways were also differentially mediated.

Using TIMSS (2007) data to look at eight countries (Australia, Colombia, Egypt, England, Hungary, Korea, Turkey and USA) [Shin and Slater \(2010\)](#) found that neither the time that principals spent on instructional leadership (e.g., developing curriculum and pedagogy) nor the time they spent supervising and evaluating teachers and other staff were related to student achievement.

Elements to relate other aspects of principal's work to attainment have also not been particularly successful. [Sealy et al. \(2016\)](#) used the 2012–13 PISA-TALIS link study data to look at the relationship between principal job satisfaction and attainment, but found a significant relationship in only 2 out of 8 participating countries.

While the relationship between leadership and attainment remains questionable from this data, there is some evidence from international studies of a significant relationship between leadership and other variables relating to school and teacher effectiveness through which leadership could have an indirect effect on pupil outcomes.

Using TALIS 2018 data, for example, [OECD \(2021b\)](#) report a positive correlation between teacher autonomy, innovation and collaboration. [O'Shea \(2021\)](#) found a positive relationship between distributed leadership and teachers' use of innovative practices in schools. [Bellibaş et al. \(2021\)](#) found a positive relationship between principals' instructional leadership and instructional quality, while the effect of distributed leadership was mainly indirect, mediated by teacher collaboration and job satisfaction. Using the same dataset, [Liu et al. \(2021\)](#) report that distributed leadership and instructional leadership were both positively and directly associated with teacher job satisfaction and teacher self-efficacy.

[Maslowski et al. \(2016\)](#) in their report on TALIS 2013 note the relationship between instructional leadership and teacher collaboration. They also found a relationship between instructional leadership and the extent to which principal feedback leads to positive change in instructional practices. Distributed leadership, in turn, was related to better staff-student relationships and a greater sense of shared purpose in the school. Similarly, [Bellibas and Liu \(2018\)](#) found a positive relationship between distributed leadership and staff mutual respect, but not with school safety, while [Sun and Xia \(2018\)](#) show a positive relationship between teacher self-efficacy and job satisfaction. In their report on TALIS 2013, [OECD \(2016\)](#) point to a positive relationship between distributed leadership and sense of purpose across the school. They also found that in schools where distributed leadership was practised there were more positive relations between students and staff. Schools in which leadership included elements of both distributed and instructional leadership were more likely to show the characteristics of professional learning communities. However, they also report that principals have only limited, indirect influence on the establishment of the learning climate in the school.

Extent of instructional leadership in schools is correlated with the extent to which principals are able to involve teachers, parents and stakeholders in school decisions ([OECD, 2021b](#)), suggesting that distributed and instructional leadership are correlated with one another.

Generally, then, the LISA studies present a mixed picture of the relationship between leadership and student attainment. It is by no means clear that there is a consistent relationship in these studies, calling into question the strong conclusions often drawn about leadership effects. On the other hand, there is converging evidence of a positive relationship between leadership practices and staff satisfaction and behaviors, which one would hypothesize as benefitting pupil outcomes.

Conclusion

There are a few conclusions to be drawn from these studies.

Firstly, the frameworks used reflect current orthodoxy in educational leadership research in their emphasis on core generic aspects such as distributed leadership, taken from the prevailing consensus in educational leadership research.

Secondly, we have over time seen a reduction in the attention spent on leadership in the LISA studies, this both in the OECD and IEA. Scales and items in PISA and TIMSS/PIRLS school questionnaires which were previously devoted to leadership have been replaced by items on other important concerns, such as diversity.

Thirdly (and probably not unrelatedly), results with regards to the impact of leadership have been disappointing. There is little in the studies summarized above that would support an emphasis on leadership as a factor that can help explain differences in pupil attainment. These findings therefore somewhat contradict the bulk of research conducted outwith the LISA studies.

It has for quite some time been a given in the literature on leadership and school effectiveness that leadership has a significant impact on attainment. Furthermore, there is a general consensus (at least until recently) on what factors matter, to the extent that Leithwood et al. (2020) claim to be able to make “strong statements on educational leadership”. The findings from LISAs are far less clear, however. Invariance across countries of what leadership means is not a given, and relationships with attainment are variable.

Why is this? We can of course not come to any definitive empirical conclusions on the basis of this review of the literature, but there are a number of possible explanations.

Firstly, it is possible that the correlational nature of LISA’s does not allow the full impact of leadership on outcomes to be measured, especially as the relationship is largely indirect. However, the majority of non-LISA studies on which the claim of significant impacts are based are also cross-sectional (Muijs, 2011).

Secondly, it is possible that due to the inevitable limitations of space within a wide-ranging survey of busy professionals means that the concepts are measured by fewer items than in studies focused specifically on leadership, potentially reducing reliability. This is certainly the case in comparison to some, if not all other studies. However, careful development and selection of items, as certainly happens in the LISA studies, should at least partially mitigate this effect.

Thirdly, due to the international nature of the data the constructs may be differently understood in different countries (the frequent finding of limited invariance suggests this may be the case). However, in-country studies using LISA data tend to converge around relatively weak effects, suggesting that this too is not the full answer.

Lastly, it is possible that the rigorous measures used in LISA impose constraints that the existing leadership studies cannot meet (for example in how attainment is measured), and that other studies may therefore overestimate effects. There is also potentially an issue of publication bias in existing studies that may have led to an overestimation of effect sizes.

The fact of these disappointing results makes the lower emphasis on leadership in recent iterations of PISA and TIMSS/PIRLS understandable. However, the level of evidence in other studies, and the theoretical basis for positing a leadership effect, mean that it is nonetheless unfortunate. An interesting exercise would be to see whether some of the newer hypotheses around leadership (see Lock and Rees, 2020), could be tested in future iterations. This would be valuable as while theoretically intriguing in light of similar developments in the study of teaching and learning, they are not currently supported by much empirical evidence.

Both theoretically and intuitively it would seem that leadership is bound to matter, and non-LISA studies tend to suggest this is the case. So let us not give up on studying this factor in relation to pupil attainment, but instead seek to refine our understanding of leadership, and develop instruments and scales that are able to measure accordingly.

Introduction

This paper provides a reflection on research exploring middle leaders in schools. It begins with definitional issues and arrives at a statement of what middle leaders are and are not. On the basis of this, it then explores reviews and research since 2006 that are helpful to understand the work of middle leaders. It concludes with five trustworthy statements about middle leaders and consideration of future research. It is not a systematic review of the literature and I do not claim completeness. Rather, it is a somewhat personal narrative, but one which will consider important papers that help to understand the phenomenon, highlight conceptual and methodological issues, and make suggestions for future research and practice directions.

Middle leader definition

It is always important to define clearly the focus of a review and in the middle leader area, this is problematic. For example, [De Nobile \(2017\)](#) described differences between middle managers, middle leaders and teacher leaders. He also noted that the phenomenon is bound by context and perspective. For De Nobile, middle leaders are those people who are positioned organizationally below the principal and other senior leaders (if present), but above teachers. They differ from teachers in that they will have a defined organizational responsibility, which will typically be part of a formal role, and they differ from senior leaders in that they will retain a substantial teaching responsibility that is likely to be their main work focus ([Grootenboer et al., 2015](#)). Defined this way, middle leaders are likely to have position titles such as director of teaching and learning, curriculum coordinator, subject coordinator, domain leader, professional learning team leader, head of department, student well-being coordinator, year level coordinator and so forth, depending on context (e.g., location, school type and level). Obviously principals are excluded, but so too are deputy principals, or those with similar overseeing roles such as a head of a campus or school section. These people are better placed in a senior leadership category although some researchers include them as middle leaders (e.g., [Cranston, 2009](#)) and others note that an administrative-focused deputy principal can be less like a leader than a middle leader with significant strategic responsibilities ([De Nobile and Ridden, 2014](#)). Teachers, or teacher leaders, are also excluded. Again, there is a frustration with the literature, because it is common for definitions of teacher leaders to not make distinctions between teachers and middle leaders, with this particularly evident in North American literature ([Wenner and Campbell, 2017](#); [York-Barr and Duke, 2004](#)). There are further confusions such as: the term “leading from the middle” which can be either a system view focused on principals (e.g., [Flessa, 2012](#); [Fullan, 2015](#); [Hargreaves and Ainscow, 2015](#)), or focused on schools (e.g., [Day and Grice, 2019](#); [Edwards-Groves et al., 2019](#); [Reid, 2020](#)); the inclusion of non-teaching staff as middle leaders ([De Nobile, 2019](#)).

For this paper, middle leaders are teachers who have an additional formal organizational responsibility. The research reviewed here will conform to this definition as much as possible, unless stated otherwise.

Middle leaders in schools

In 2017, Harris and Jones in an editorial for *School Leadership and Management*, made several important observations about middle leaders. They suggested that the interest in middle leadership had faded, and that the literature on distributed and teacher leadership “may just have overshadowed and supplanted any interest in middle leadership roles” ([Harris and Jones, 2017](#), p. 214). Their paper was a call to for a renewed research effort.

Since then, *School Leadership and Management* has published a seven-article special issue edited by [Grootenboer et al. \(2017, 2019\)](#), which included a review on middle leaders ([Harris et al., 2019](#)). [Harris et al. \(2019\)](#) took, as their point of departure, the middle leader reviews conducted by Bennett and colleagues a decade earlier ([Bennett, 2005, 2006](#); [Bennett et al., 2003, 2007](#)). Before considering the review of [Harris et al. \(2019\)](#), it is worth reflecting on these earlier reviews.

The reviews of Bennett and colleagues were focused on subject leaders, middle managers, heads of department and curriculum coordinators, mostly in secondary contexts, mostly in England or comparable countries (Australia, Canada, Hong Kong, New Zealand, the Netherlands and the USA; and additionally Singapore and South Africa for the 2003 review) reporting on mostly small-scale qualitative or survey-based empirical studies from English language journals from 1988 and books from 1995. The sources for the review included six major databases: EBSCO, SSCI, ERIC, Education Line, JSTOR and SwetsWise. The initial 2003 review included 101 articles, the 2005 review added another 51 articles, with the 2006 and 2007 papers providing further review data. The conclusions arising from these reports include:

- Middle leaders can be important to schools in terms of their influence on teacher work and student learning, but the nature of this is context dependent.
- They have a focus on their responsibility area and sometimes this means there is a tension between meeting expectations at the whole school level and supporting their area. Senior leaders want them to be involved more broadly in whole-school matters, but the middle leaders are more comfortable with a focus on their responsibility area.
- Relatedly, there is tension between line management demands and the collegiality these leaders seek to foster. This is shown by increasing supervisory and accountability requirements (often enacted through observation of colleague's work) in competition with the desire and need to work collaboratively with colleagues in improving teaching and learning.
- These teachers will often have doubts about whether they have sufficient teacher competence and subject knowledge to be advising others.
- There was a need to study the influence of this leadership work on teaching and learning, and to understand the effectiveness of the professional development of middle leaders.

From these reviews, it seemed that middle leaders were acknowledged as being potentially important to school success, but with some caveats related to context, expectations, support and tensions; that is, middle leaders can positively influence teacher work and student learning, but this depends on how their role is constructed and how they are selected and supported in the role to do this influence work. I will return to consider evidence about the impact of middle leaders later in the paper.

The review of [Harris et al. \(2019\)](#) builds upon this work by Bennett and colleagues and reflects the changing nature of academic publications. They relied on journal articles that were English language, published, peer-reviewed, empirical and available through searches on EBSCOHOST, Web of Science, SCOPUS and six further education databases. The journal scope was perhaps broader than the earlier reviews, but the review was narrower in that other "materials such as books, masters and Ph.D. theses, conference proceedings, policy papers and articles published in non-ISI/SCOPUS journals were excluded" ([Harris et al., 2019](#), p. 270). The review by [Harris et al. \(2019\)](#) departs from the earlier reviews in that it is largely a quantitative exercise identifying broad trends in regard to knowledge production on middle leadership in schools; it does not provide the more nuanced perspectives that Bennett and colleagues gained from reading their review papers closely. Their criteria for inclusion meant that the [Harris et al. \(2019\)](#) review used 49 articles. The review did not provide bibliographic details about all the papers reviewed. As is the trend of late with science mapping reviews (e.g., [Kovacević and Hallinger, 2020](#)), it is a bibliometric review that is absent of substantial content. Rather, it reports on patterns and connections. Findings included:

- The amount of research increased but not greatly; there were 2.8 publications per year between 2003 and 2007 (5 years), compared to 3.5 publications per year between 2008 and 2017 (10 years).
- Nearly 50% of papers were published in journals that are not within the field of educational leadership, although the main journal for publication was *School Leadership and Management* with 22% of the publication; this is a journal strongly connected with the UK.
- Most research was published in the UK, although increasing country diversity was evident (especially from Asian and Middle East countries post-2007)
- 43 of the 49 articles used qualitative or mixed-methods, with the most common methods being interview. Post 2007, there was an increase in use of more diverse methods with interviews being supplemented with observation and document analysis.
- More than half were focused on leadership practice and roles, with other areas of focus including professional development/agency, professional identity, culture and leadership distribution.

There are reviews and reports of research streams published after the reviews by Bennett and colleagues that provide some of the rich detail missing from the review of [Harris et al. \(2019\)](#), and it is these to which I now turn. In the following paragraphs, I describe a broadly focused middle leader review by [De Nobile \(2017\)](#), before considering examples of two research programs; the practice architecture research by [Grootenboer et al. \(2019\)](#), and a series of doctoral research from Australia ([Gurr, 2019](#); [Gurr and Drysdale, 2013](#)). I conclude by exploring leadership impact studies by [Dinham \(2005, 2007\)](#) and [Highfield \(2012\)](#), and [Leithwood's \(2016\)](#) review of secondary school heads of departments.

De Nobile has produced a middle leadership review ([De Nobile, 2018](#)), constructed a model informed by the review ([De Nobile, 2017, 2018](#)) and is developing a questionnaire ([De Nobile, 2019](#)). The 2018 review was modeled on the work of [Bennett et al. \(2003\)](#) and involved a search of databases from 2003 to 2016 that included ERIC, A+ Education, EBSCO, JSTOR and Informit. The search uncovered 252 journal articles, book articles and books, institutional reports, and school system reports. Search terms began with middle management and middle leadership but were expanded to include more publications by using typical middle leader positional terms such as department head, subject leader, year advisor. Teacher leader and teacher leadership were also included as search terms and this, unfortunately, leads to some doubts about the veracity of the findings in terms of middle leaders. Through

content analysis of definitions, descriptions, findings, recommendations and practices relating to middle leadership, and recording of publication demographics, a comprehensive review was provided. The review did not provide bibliographic details about all the papers reviewed, with only about half the reference details provided in [De Nobile \(2017, 2018\)](#). Findings from the review included:

- A decrease in publications between the periods 1999–2007 and 2008–2016. Note that the longer time frame compare to [Harris et al. \(2019\)](#) suggests a different pattern.
- Of the 234 publications with a single country focus, most were from the UK (42%), Australia (26%) and the USA (12%). Note, this review has not identified the increasing diversity found in [Harris et al. \(2019\)](#).
- Most publications were in academic journals (67%), books (10%) or reports (8%).
- Publications were research reports (73%), reviews (14%), conceptual papers (9%) or policy papers (4%).
- Publications were focused on primary and secondary schools (36%), secondary schools (34%) or primary schools (15%).

There were also findings in regard to terminology use. [De Nobile \(2018\)](#) noted both the overlap and distinctiveness between teacher leadership and middle leadership research, yet, as noted already, included teacher leadership in his search terms. [De Nobile \(2018\)](#) found that middle manager was the preferred term from 1999 to 2005 and was then supplanted with the emergence of middle leader and teacher leader such that by 2008 the term middle manager had largely vanished. [De Nobile \(2018\)](#) suggested that the terms middle leadership and teacher leadership were becoming interchangeable.

The review by [De Nobile \(2018\)](#) then focused on reporting evidence that informed the middle leader model. [De Nobile \(2017, 2018\)](#) describes an input/output role model that helps to clarify the influences on the work of middle leaders:

- **Inputs:** principal support, school/system culture, professional development, enthusiasm/drive, and knowledge of curriculum, pedagogy and assessment.
- **Roles:** student focused, administrative, organizational, supervisory, staff development and strategic. These are ordered from managerial to leadership.
- **Enactment of roles:** managing relationships, leading teams, communicating effectively, managing time and managing self.
- **Outputs:** teacher quality, teacher attitudes and student outcomes.

[De Nobile \(2018\)](#) provides some of the evidence base for each element of the model and there is further clarification in [De Nobile \(2019\)](#). Suggestions for further research centered on quantitative and qualitative empirical research to confirm and develop the model ([De Nobile, 2018, 2019](#)). Input/output middle leader models have been developed before, such as those focused on heads of departments by [Turner and Bolam \(1998\)](#) and [White \(2000\)](#).

A different approach to researching middle leaders is found in the work of Grootenboer and Edwards-Groves from Australia, and Rönnerman from Sweden. Over several years they have used practice architectures to explore the interactions between persons, practices and contexts (e.g., [Edwards-Groves et al., 2019](#); [Grootenboer, 2018](#); [Grootenboer et al., 2017](#)). In practice architectures, beliefs (sayings), practices (doings) and relationships (relatings) in various contexts (including temporal) need to be considered. This view is not dissimilar to Spillane's interaction approach to researching distributed leadership ([Spillane, 2006](#); also see [Grootenboer, 2018](#), p. 24), and, indeed, [Edwards-Groves et al. \(2019\)](#) view their research as extending Spillane's research. This work is mostly small scale and interview-based, often in primary settings, sometimes using action-research and sometimes focused on how middle leaders support professional learning of their peers. Surprisingly given the practice focus, while observation may be included in the research, sometimes the observations are not used to inform the findings (e.g., [Edwards-Groves et al., 2019](#)). [Grootenboer \(2018\)](#) provides a complex view of this research in a book about the practices of school middle leaders that uses a varied (conceptually, methodologically and in terms of the research and school focus) collection of five studies. He describes three broad practices of middle leaders related to leading teaching (termed leading-teaching to emphasize simultaneous work in both leading and teaching), managing and facilitating, and collaborating and communicating, with a focus on curriculum development and professional development of teachers. This is explained in [Grootenboer et al. \(2017, p. 248\)](#) as:

The practice of middle learning involves engaging in (simultaneous) *leading-teaching* by *managing and facilitating* educational development through *collaborating and communicating* to create communicative spaces. [italics from original]

Communicative spaces are where the practice of middle leading occurs. [Grootenboer \(2018\)](#) provided many examples of practice from the five studies that informed the book.

Doctoral research is often not represented well in reviews, yet they can make a significant contribution. As an example, I will refer here to a doctoral research series exploring middle leaders that Drysdale and I have supervised, and, later in the paper, to a thesis by [Highfield \(2012\)](#). [Gurr \(2019\)](#) reported on a sequence of six doctoral theses over a 20-year period that focused on the work of middle leaders (the five published theses are [Cotter, 2011](#); [Huerta Villalobos, 2018](#); [Keane, 2010](#); [Koh, 2018](#); [White, 2000](#)). This built upon an earlier report by [Gurr and Drysdale \(2013\)](#). All studies utilized multiple-perspective interviews. Four were from secondary schools in Melbourne, Australia, one researched primary schools in Singapore and one researched secondary schools in Chile. All were focused on teachers with middle leader roles who were leading curriculum or learning areas, and one also included teachers in pastoral roles. The review found that increasingly middle leaders were being viewed as key personnel in improving teaching and learning, and when they had well-defined roles and sufficient expectation and support could impact on

student outcomes through providing direction, leading professional support and focusing on improving teaching practice. Conclusions about student impact were based on perception and not through formal evidence of learning gains. Unfortunately, a consistent finding over the two decades covered was that too often the middle leaders had limited impact on improving teaching and learning, did not receive sufficient support from senior leaders, and worked in school structures that hindered their work. To support the development of middle leaders it was suggested that they needed to be career focused, supported in their development by principals and other senior leaders, with access to appropriate professional learning programs, supported in a student-focused school culture and structure, and with clearly defined and high expectation role descriptions.

What is surprising in the middle leader research is that there is often little said about the impact of middle leaders on student learning. Mainly the evidence is centered on their influence on colleagues, and then anecdotally on students. There is an assumption that this work then leads to positive impacts on student learning (Day and Grice, 2019). There is, however, some research that makes a more substantial case for impact on student learning and three examples are explored below (Dinham, 2005, 2007; Highfield, 2012; Leithwood, 2016).

One of the most compelling studies in terms of the impact of middle leaders has been the ÆSOP (An Exceptional Schooling Outcomes Project). ÆSOP involved the study of 50 subject departments and cross-school programs (e.g., student welfare) in years 7–10, across 38 secondary schools in New South Wales, Australia (Dinham, 2005, 2007). Initial selection of the 50 “sites” was based on a combination of reputation (nomination from parent groups, principals, system officers) and analysis of publicly available data on student achievement (public examination performance and value-adding data) that demonstrated outstanding educational outcomes over at least a 4-year period. The study involved a reflection on what influenced the achievement of these results. Multiple-perspective, individual and group interviews involved the principal, head teacher/leader of the outstanding department/program, staff group forum, two student forums (year 7/8 and 9/10 groups), parent forum, classroom observation and document analysis. Principal leadership (Dinham, 2005), and leadership of the Heads of Department/Programs (Dinham, 2007) were both important for student success. The middle leaders were found to promote success through a combination of core and contributing strategies (Dinham, 2007).

Core strategy

- A focus on students and their learning across academic, personal and social dimensions.

Contributing strategies

- High-level interpersonal skills, and generally being well-liked and trusted.
- High-level professional capacity and strategic resource allocation.
- Promotion and advocacy of their departments and maintaining good external relations with the school.
- Influencing department planning and organization.
- Developing common purpose, collaboration and sense of team within their department.
- Fostering teacher learning and developing a culture of shared responsibility and trust.
- Clear vision, high expectations of themselves and others, and developing a culture of success.

While the focus of the research was on the outstanding faculties and teams, it also found that principal, and other senior leadership support, were important contributors to site success. Principal leadership that supported middle leader success included (Dinham, 2005):

- Having a core focus on students and their learning across academic, personal and social dimensions.
- External awareness and engagement with the wider environment
- A bias toward innovation and action
- High level interpersonal skills, and generally being well-liked and trusted
- Having a clear vision, high expectations and fostering a culture of success
- Encouraging teacher learning and responsibility, and showing trust
- Promoting student support, developing common purpose and encouraging teacher collaboration

Dinham (2007) noted the significant overlap between the strategies of middle leaders and principals, with the main difference being that middle leader work was, understandably more focused on their area responsibility than the wider school, albeit that some middle roles have a whole-school focus (e.g., student welfare). This research highlighted both how middle leaders contribute to teacher and student success, and the importance of the principals and other senior leaders in “providing the conditions where teachers can operate effectively and students can learn” (Dinham, 2005, p. 355).

A study that provided estimates of the impact of middle leaders on student learning was a quantitative New Zealand study on secondary Heads of Department by Highfield (2012). This is another example of doctoral thesis research, and, in this case, provides findings that build upon the qualitative ÆSOP study (as noted by Highfield, 2012). Drawing upon literature on within-school variation and middle leaders, Highfield (2012) constructed a three-phase study. The first explored within-school variation in English, mathematics and science departments in 41 secondary schools. The second phase used 10 of the 41 schools that volunteered to be involved in a survey-based exploration of middle leadership practices; 95 (87%) middle leaders, and 232 (65%) teachers completed complementary surveys on middle leader practices. The third phase connected middle leadership practices with student achievement. Middle leadership was mostly found to contribute positively to student learning. For the last two years of secondary schooling, middle leadership practices were shown to explain an important amount of student achievement variation; for the third

last year of secondary school there was no significant relationship found. At Level 2 NCEA (equivalent to the second last year of secondary schooling), while school decile (a measure of school community socio-economic status and educational advantage) accounted for 62% of variance in student academic outcomes, middle leadership accounted for an additional 22%, while at Level 3 NCEA, school decile accounted for 46% and middle leadership 16% of variance. Highfield (2012, p. 155) concluded that,

a combination of school decile and middle leadership practices were strong overall predictors of student academic achievement at Level 2 and 3 NCEA. This is a critical finding of the study because it demonstrates that middle leaders and the teachers in their departments can make a difference to student academic outcomes despite the socioeconomic status or ethnicity of students.

The most important leadership practices impacting positively on student outcomes were management of resources, goals and expectations, and creating a positive learning environment for students and teachers. Negative impacts were, surprisingly, compared to other research (e.g., Bennett, 2005; Dinham, 2005; Tay et al., 2020), associated with practices that promote collegiality among teachers, and a focus on academic results.

Leithwood (2016) conducted a review of research focused on secondary department heads to address a lack of attention to this middle leadership role. The review overlaps considerably with other reviews and some of the research already noted; for example, the research of Dinham (2007) and Highfield (2012) are represented in the review, as is much of the earlier UK research on department heads such as the work of Siskin (1991, 1997) and Brown and Rutherford (1998), which were included in the review by Bennett et al. (2003). Leithwood (2016) searched five educational leadership journals (*Educational Administration Quarterly*, *International Journal of Leadership in Education*, *School Leadership and Management*, *Educational Management, Administration and Leadership*, *Management in Education*), three other education journals (*School Effectiveness and School Improvement*, *Journal of Educational Research*, *Educational Researcher*), and the ERIC, Proquest and Google Scholar databases. The period of review seems to have covered at least 30 years, with some studies from the mid-1980s included. The review uncovered 42 studies (29 qualitative, 7 quantitative and 6 mixed-method), with most of the studies from the UK (16) and the USA (16). Additionally, 15 literature reviews and 10 related studies were used to inform the findings. It was suggested that contextual differences across countries were less important than differences in teaching cultures, union regulations, and department head and principal expectations about the role. Effective leadership practices were described by matching research evidence from 32 relevant studies with the Ontario Leadership Framework (OLF) (Leithwood, 2012), with Leithwood (2016, p. 131) suggesting that,

... effective department-head leadership practices and personal leadership resources are closely aligned to those practices and resources included in the OLF. Most of the differences are a reflection of the "middle leader" position of the department head in the school. This position creates a unique need to build productive relationships with individual teacher colleagues and heads of other departments, and to forge a significant school-wide decision-making role for themselves in collaboration with school-level leaders who have considerable discretion in determining how much authority to award their department heads.

Leithwood (2016) concluded that

"department and department-head effects on students are consistently positive, practically meaningful and larger than school effects" (p. 117), and "that secondary-school principals and department heads, acting in concert, maybe especially well-situated to provide both instructional and transformational leadership practices and, as a consequence, make powerful contributions to secondary-school improvement" (p. 136).

Like Dinham's (2005, 2007) research, and findings from other studies (e.g., Bassett, 2016; Cotter, 2011; Keane, 2010; White, 2000), it seems that having leadership expectations of the role that are shared by middle leaders and principals (and other senior leaders), and operating in a supportive environment, are especially important if middle leaders are to impact positively on teaching and learning. Leithwood (2016) distinguished between middle leaders that evaluate and supervise teachers versus those that offer collegial support and guidance, with the former having a far greater impact on teaching and learning. Relatedly, Farchi and Tubin (2019) found that successful schools tended to have middle leaders who focused more on pedagogical behavior than administrative behavior.

Reflection

The call from Harris and Jones (2017) for more middle leader research remains worthwhile, but it is clear from this and other reviews that there is a substantial existing knowledge base. Considering the state of knowledge from the reviews by Bennett and colleagues, there is some development since, but perhaps not as much as would be expected over the 13 years since 2007. The nature and extent of the development in knowledge, however, is somewhat dependent on review methodology, especially in relation to time period comparisons, what type of publications are included, and, for journals, which journals are included. Nevertheless, there is more clarity about the influence of middle leaders on teacher work and more certainty about their impact on

student learning—although the extent of both influences remains context dependent. Compared to the earlier reviews, increasingly middle leaders are being expected to be involved in whole-school as well as area responsibilities. The tension between supervision *of* staff versus collaboration *with* staff remains, although increased use of collaborative structures and enhanced knowledge of teaching and learning are enhancing the work of middle leaders and possibly reducing this tension.

Without overstating the knowledge base, in 2020 there are several trustworthy statements that can be made about middle leaders (indicative references provided):

1. Middle leaders can impact positively on teacher work and student outcomes (Carter, 2016; Dinham, 2005, 2007; Highfield, 2012; Leithwood, 2016). Indeed, they are an important source of leadership impact on student outcomes in many school contexts, and especially so when principals and middle leaders act together (Leithwood, 2016).
2. The way middle leaders improve student outcomes is through establishing the conditions (e.g., area direction, resource acquisition and distribution, staff development, supportive culture) that lead to collective endeavor by a group of teachers to improve teaching and learning (Bryant et al., 2020; Dinham, 2005; Grootenboer, 2018; Grootenboer et al., 2017; De Nobile, 2017, 2018; Gurr, 2019; Gurr and Drysdale, 2013). Developing staff collegiality can also have many benefits, but to have a positive influence on student outcomes this needs to have a focus on improving teaching and learning (Highfield, 2012; Leithwood, 2016).
3. High expectations and role clarity are important for these people to have a leadership focus rather than a managerial or administrative focus (Farchi and Tubin, 2019; Gurr, 2019). High expectations come from both the middle leaders themselves in terms of their sense of agency, and from principals and senior leaders about what they want from the roles (Gurr and Drysdale, 2013). Principals working in concert with middle leaders enhances the success and impact of middle leaders (Bassett, 2016; Dinham, 2007; Leithwood, 2016). Role clarity serves to give balance to leadership and management functions (Drysdale et al., 2016; Farchi and Tubin, 2019).
4. Recruitment and professional development are important both in terms of the quantity and quality of middle leaders (Gurr and Drysdale, 2013; Rhodes and Brundrett, 2009). To ensure there are sufficient teachers who have the skills and characteristics to be successful middle leaders there is a need to encourage teacher aspirations, have appropriate selection and induction processes, and ensure there is on-going review and development (Bassett and Robson, 2017; Gurr and Drysdale, 2013; Ng and Chan, 2014; Rhodes and Brundrett, 2009; Thorpe and Bennett-Powell, 2014).
5. There are factors that diminish the effectiveness of middle leaders with these being the negative of many of the factors noted above. These factors include a lack of understanding and organizational support by senior leaders, lack of professional preparation and leadership development, underdeveloped professional knowledge and capability, and a focus on administrative practices.

While there are some differences across the reviews about where the research is originating, there is a consistent presence of research from the UK over the past three decades. There is also likely to be a substantial contribution from the USA, although this is obscured somewhat with the focus on teacher leaders in preference to distinguishing between teacher and middle leaders. There is a consistent contribution from Australian researchers, with a notable increase from about 2017. Also evident from 2007 is the expansion of the knowledge base to include research from Asia and the Middle East. Of course, this is reporting upon research written in English language journals. A more complete review is needed that includes a more diverse language background, such as research published in Spanish and Chinese.

The research is dominated by qualitative and mixed method research, especially the use of interviews. In recent years, more diversity is evident with observation and document analysis being used along with interviews. Mixed method research, while not as prevalent, continues and the careful work of De Nobile (2017, 2019) is an example. Nevertheless, future research may need more innovative methods as indicated below.

While an effort has been made to only include middle leader research in this paper, some ambiguity is evident with, for example, the review by De Nobile (2018) deliberately including teacher leadership literature. This highlights an ongoing issue for middle leader research. There is, no doubt, considerable overlap between teacher leader, distributed leadership and middle leader research. It is not easy to resolve the overlap and what it means for the knowledge of leadership in schools—the segmentation allows for detail to be explored but may be artificial compared to the reality of working in schools. It is understandable that De Nobile (2018) wanted to expand his review by including teacher leadership, as there is literature in this area, which is relevant to a study of middle leaders, especially from the USA where teacher leadership is a broad term (Murphy, 2005; Wenner and Campbell, 2017; York-Barr and Duke, 2004). Yet, it also means that his review was not entirely focused on middle leaders because he gave no sense of how he might have vetted the teacher leader papers for their suitability to inform knowledge about middle leaders.

It is also understandable to seek to include research about leadership distribution. For example, the distributed leadership literature, while also suffering from conceptual confusion has much to say about the how non-principal leadership impacts on schools (Tian et al., 2016). While there is evidence through social network analysis that many in schools can have substantial influence (Supovitz et al., 2019), there is also evidence that middle leaders are important (Bryant et al., 2020; Nicholas, 2019). For example, Nicholas (2019) conducted a network analysis across three successful secondary schools which involved a total of 186 staff completing an eight-question network instrument. He then interviewed 26 highly connected staff about their work. In terms of the 20 most highly connected people in each school, there were only two people out of the 60 that didn't have a senior (7 people)

or middle leader (51 people) role. Being connected allows for leadership opportunities, and so the idea that “true” teacher leaders are common is clearly not the case. It is also clear that from a distributed leadership perspective, middle leaders are likely to be an important source for study.

Perhaps the contemporary reality of many schools, with increased use of collegial/collaboration arrangements (e.g., Hargreaves and O’Conner, 2018), means that dividing leadership research into principal, senior leaders, middle leaders and teacher leaders, and focusing on the distribution of leadership, is no longer sufficient. More holistic research is called for and this may benefit from a practice focus such as the interaction perspective of distributed leadership researchers (e.g., Spillane and Zuberi, 2009) or the practice architecture approach (e.g., Grootenboer, 2018). This will likely require innovative research strategies that can, in unobtrusive ways, collect rich practice data. In terms of ways to conceptualize middle leaders, while general leadership models can be adapted and used to locate the work of middle leaders (e.g., Gurr and Drysdale, 2013), and there are middle leader specific models (De Nobile, 2017, 2019), non-positional and relationship focused leadership models (e.g., Angelle and DeHart, 2016) and practice community views (e.g., Hord and Summers, 2008) are likely to become important to gain a better understanding of the work of middle leaders.

The writing of this paper predates the publication of another review of middle leaders (Lipscombe et al., 2021). The conclusions of the current paper are not changed by this more recent review, but there are additional details about the impact, work and characteristics of middle leaders that readers will find useful.

Introduction

The concept of ‘system leadership’ is one that over the past two decades has caught the educational imagination. System leaders are those Heads or Principals who are willing to shoulder system wide roles in order to support the improvement of other schools as well as their own. As such, system leadership is a new and emerging practice that embraces a variety of responsibilities that are developing either locally or within discrete Local/State/Regional networks or policy driven initiatives that when taken together have the potential to contribute to system transformation.

The educational policy direction in many developed countries is changing quite dramatically at the present time (Harris and Jones, 2017; Hopkins, 2013; Schleicher, 2018). There is currently a rapid shift away from the government managed educational changes of the 1990s and 2000s to far more decentralised systems based on the principle of ‘autonomy’. This reflects the genuine belief on the part of many politicians and policy makers that there is a need to unleash the power of the profession that has been harnessed in the recent past by too much control. It is within such a context that system leadership assumes increasing importance.

The education leadership field is subject to fads and fashions that quickly come and swiftly go. In sharp contrast, the leadership models that have a sound and extensive empirical base tend to converge around a few core leadership areas (Leithwood et al., 2019). A systematic review of the evidence conducted by Gumus et al. (2018) concluded that distributed leadership, instructional leadership, teacher leadership and transformational leadership continue to be the most researched models of leadership. The review also found that empirical interest in all these leadership models has increased significantly over the past decade further strengthening the collective evidence base.

While system leadership does not feature in the current list of most researched models of leadership, it certainly remains a very popular idea and is still reflected in the policy landscape of many countries. Its presence is still evident in much of the contemporary writing about educational and organisational change.

Since its emergence in the early 2000s, system leadership was viewed as an important system driver and as a means of building the system capacity required for positive change. In 2008, the OECD undertook a significant research program and produced two volumes about system leadership, one of these volumes included a range of detailed country cases (Pont et al., 2008a, 2008b). At this time, prominent academics and influential policy makers endorsed the idea by writing about the processes, practices, and impact of system leadership in action (e.g. Fullan, 2005; Higham et al., 2009; Hopkins, 2009). The term ‘system leadership’ also links to earlier work on systems thinking and has strong connections with systems theory (Senge, 1990).

This chapter outlines the development of the concept of System Leadership and reviews the current international evidence base. In making the case for the potential of system leadership as the key driver for systemic reform the argument in this paper is divided into three key sections:

- **Part 1** outlines the genesis of System leadership pre-2010, in particular:
 - Explores emerging definitions of system leadership
 - Conceptualises its contribution to systemic reform
 - Describes its emergence in a case study of England
 - Reviews its emerging practice by referring to the 2008 OECD School Leadership study.
- **Part 2** reviews the literature post 2010 as the concept of system achieves maturity and is better embedded in policy reforms in many countries
- **Part 3** identifies future challenges.

Part one

Defining system leadership

System leadership, in the sense it is used in this chapter, implies a significantly more substantive engagement with other schools in order to bring about system transformation. Specifically, we define it as a form of leadership where a head teacher or principal is willing and able to shoulder wider system roles and in so doing is almost as concerned with the success and attainment of students in other schools as they are with their own.

Although the concept of 'system leadership' began to catch the educational imagination in the early 2000s it was not initially defined with such clarity. At this time, it was seen more as an emerging role, an instinct or aspiration rather than an operational job description. Take for example these quotations from two significant opinion makers. The first from the General Secretary of the Association of School and College Leaders in England and the other from a leading educational commentator whose work has a global reach.

[John Dunford \(2005\)](#) in an address to the National Conference of the Specialist Schools and Academies Trust (SSAT) argued that:

The greatest challenge on our leadership journey is how we can bring about system improvement. How can we contribute to the raising of standards, not only in our own school, but in others and colleges too? What types of leaders are needed for this task? What style of leadership is required if we are to achieve the sea-change in performance that is demanded of us?

In *Systems Thinkers in Action* [Michael Fullan \(2004\)](#) argued that:

a new kind of leadership is necessary to break through the status quo. Systematic forces, sometimes called inertia, have the upper hand in preventing system shifts. Therefore, it will take powerful, proactive forces to change the existing system (to change context). This can be done directly and indirectly through systems thinking in action. These new theoreticians are leaders who work intensely in their own schools, or national agencies, and at the same time connect with and participate in the bigger picture. To change organizations and systems will require leaders to get experience in linking other parts of the system. These leaders in turn must help develop other leaders within similar characteristics.

These two quotes reflect the more tentative and emerging concept of the role in the early 2000s. The Dunford quote asks about future styles of leadership without proposing any answer to the question. The Fullan quote mentions the importance of leaders engaging in systems thinking but does not allude to the concept of system leaders developed in this chapter.

These quotations do however contain three implicit and important assumptions relevant to the emerging concept of system leadership. The first is that if we are ever to achieve sustainable education change it must be led by those close to the school [this is an explicit claim made by Fullan] the second is that this must have a systemic focus [also an explicit claim by Fullan]; the third is that "system leadership" is an emerging practice [that reflects the challenge implied by Dunford's questions].

Despite this tentativeness, system leadership as a concept has a rich theoretical and research context. The conceptual concerns of system theory for relationships, structures and interdependencies ([Katz and Kahn, 1966](#); [Senge, 1990](#); [Campbell et al., 1994](#)) underpin the contemporary work of system leaders in practice. The key insight here has been well summarised by [Kofman and Senge \(1995:27\)](#) when they state that the "... defining characteristic of a system is that it cannot be understood as a function of its isolated components. ... the system doesn't depend on what each part is doing but on how each part is interacting with the rest".

These demands are further illuminated in theory by [Peter Senge \(1990\)](#), who argues that for organisations to excel, they have to become "learning organisations", which he defines as "organisations where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning to see the whole together" (p. 3). To Senge, the key to becoming a learning organisation is for leaders

to tap into people's commitment and capacity to learn at all levels, to clarify broader systemic interdependencies and how to make them more effective (ibid, p. 4).

This theme, as seen in the quote above, underpins Fullan's (2005) exposition, in a later publication than the previous quote, of the role he believes school leaders will need to play as "system thinkers in action" if sustainable large-scale reform is to be achieved. This, Fullan argues, will necessarily involve adaptive challenges that "require the deep participation of the people with the problem; [and] that is why it is more complex and why it requires more sophisticated leadership" (p. 53). For Fullan, examples of this new work include:

- Leading and facilitating a revolution in pedagogy (p. 57)
- Understanding and changing the culture of a school for the better (p. 57)
- Relating to the broader community, in particular with parents, and integrating and co-ordinating the work of social service agencies into the school as a hub (p. 61)
- This will demand "... above all ... powerful strategies that enable people to question and alter certain values and beliefs as they create new forms of learning within and between schools, and across levels of the system" (ibid, p. 60).

The challenges that Fullan posits represent an ambitious agenda and, as will be seen later, not all "system leaders" take on all these roles. This list also begs the question - Are there enough Heads or Principals with the existing or potential dispositions and capacities, required to achieve such an ambitious set of expectations to lead the huge numbers of existing schools? This is not only an adaptive challenge, but also a logistical one. Our response, as is seen in Part Two of this chapter, is that there is no expectation that every Head or Principal will be a system leader, that would be both unrealistic and unnecessary. What however is both realistic and necessary is that a significant minority of such leaders adopt elements of this role if we are to move toward system transformation.

So, this discussion of system leadership is leading us to three initial conclusions. First the concept of system leadership flows from the general literature on systems theory and thinking. Second system leadership is a theory of action that embraces a range of disciplines in order to exert its power (see for example Elmore, 2004; Leithwood and Riehl, 2005). And third, system leadership will only exert any influence to the extent that it focuses on teaching and learning (i.e. is instructional), shares its authority with others (i.e. is distributed).

These assumptions lead to three other observations that are discussed in detail in this chapter. The first is that there is a tension between system leadership being a national policy or a professional movement. This dichotomy as we will see has profound implications for the prospect of sustainable educational reform. The second is that although system leadership is emerging as a professional practice, it is a concept that as we have seen is located in a rich theoretical and research context. The third observation is that while many school leaders in most jurisdictions are involved in some form of collaborative activity or networking, this is categorically not the same as system leadership. We continue to explore these observations in the following sections of the chapter.

System leadership for system transformation

As has been noted already, the concept of system leadership emerged in the early 2000s, at a time when the long-term utility of large-scale top-down change was being questioned (Fullan, 2011; Hopkins, 2007; Sahlberg, 2012).

There is a general lesson to be drawn for large scale/systemic reform from the global experience in the early 2000s. It is that top-down large-scale reform which has an early narrow focus on key measurable skills can produce a rapid increase in standards at least initially. However, this initial rise in standards will inevitably level off over time if top-down micro-management becomes the default change strategy.

To move beyond this inevitable plateau of achievement requires a system wide school improvement approach that can deliver continuous improvement beyond the early gains. In other words, large scale reform has characteristically focused on short term objectives, whereas systemic change envisages a multi phased process that ensures that early gains do not level off but continue to improve as a consequence of employing strategies that at the same time raise achievement and build capacity.

However, achieving this shift is not straight forward. As Michael Fullan (2003:7) has said, it takes capacity to build capacity, and if there is insufficient capacity to begin with it is folly to announce that a move to 'professionalism' provides the basis of a new approach. The key question is 'how do we get there?', because we cannot simply move from one era to the other without self-consciously building professional capacity throughout the system.

This analysis is informed by the English experiment with large scale reform in the late 90s/early 2000s. The argument goes something like this (Hopkins, 2007):

- Most agreed that standards were too low and too varied in the 1990s and that some form of direct state intervention was necessary.
- However, when progress inevitably plateaued one has to question whether prescription, or more micro-management still guaranteed sustained large-scale reform in the medium term.
- The answer of course is to re-balance top down and bottom up and as competence and confidence increases give more responsibility to schools and system leaders to lead improvement efforts.

Fig. 1 Toward system wide sustainable reform.

It is this progression that is illustrated in Fig. 1, where system wide reform is driven by system leadership. The intent of the diagram is to indicate that when a school or system is under performing i.e. has low levels of local capacity, then national prescription is necessary. As local capacity increases however, national prescription needs to gradually be replaced with local discretion. This is the re-balancing that is implied as one moves from the left-hand to the right-hand side of the diagram.

It is worth taking a little more time unpacking the thinking underlying the diagram. Five points need making.

The first is to emphasise that this not an argument against 'top down' change. It is clear that neither 'top down' nor 'bottom-up change' work just by themselves, they have to be in balance – in creative tension. The balance between the two at any one time will of course depend on context.

Secondly, it must be realised that in England in 1997 it was obvious that more central direction was needed. This reflects the balance toward national prescription as seen in the left-hand segment of the diagram.

Third it should be no surprise to realise that the right-hand segment is relatively unknown territory. It implies horizontal and lateral ways of working with assumptions and governance arrangements very different from what we know now. The main difficulty in imagining this landscape is that the thinking of most people is constrained by their experiences within the power structure and norms of the left-hand segment of the diagram.

The fourth point is both complex and critical. In terms of the diagram, effective system wide sustainable reform requires a movement from the left to right with all that implies. The left to right movement is necessarily incremental as it builds on, rather than contradicts, the success of previous phases. Yet, and this is the crucial point, the achievement of creating the educational landscape implied by the right-hand segment represents a step change from what has gone before. Yes, the difference between left and right-hand segments represents a radical change or a transformation; but the process or journey from left to right will be incremental, building on past success and re-shaping in light of learning from experience. It is in this way that the language of school improvement (logical incremental steps building on past experience) and transformation (a qualitatively different state from what was known previously) is reconciled.

Finally, of course it is not being suggested that one always has to start from the left-hand side of the diagram and move in some sort of uniform way to the right. That is just how it was in England in 1997. Other systems may well be in the middle and need to move left briefly to firm up certain conditions before rapidly proceeding into the right-hand segment. Some may believe that they are already in the right-hand segment. If this diagram has any value, it is as a heuristic – its purpose is to help people think rather than tell them what to do.

One further point needs to be re-iterated. As noted earlier, the transition from 'prescription' to 'professionalism' is not straight forward. In order to move from one to the other, strategies are required that not only continue to raise standards but also build capacity within the system. This point is key, one cannot just drive to continue to raise standards in an instrumental way, one also needs to develop social, intellectual and organisational capital. This also explains why the concept of "school-based management" by itself is insufficient to affect the transition from the left hand to the right-hand side of the diagram. It is system leadership rather than management that is required.

The emergence of system leadership – the case of England

It was a policy context such as that described above that led to the emergence of System leaders in England in the early 2000s. At this time Ministers deliberately, strategically and boldly embraced the logic of [Fig. 1](#), re-balanced top-down/bottom-up change policy initiatives and embraced system leadership and entered into a new relationship with schools.

In *Every School a Great School* ([Hopkins, 2007](#)) it was suggested that the five striking characteristics of system leaders, those distinguishing them from broader collaborative activity, are that they deploy their experience, knowledge and skills to:

- actively lead improvements in others schools and measure their success in terms of student learning, achievement and welfare, both to raise the bar and narrow the gap(s).
- commit staff in their own and other schools to the improvement of teaching and learning, engaging them deeply in the organization of teaching, learning, curriculum and assessment so as to ensure learning is increasingly personalized for students.
- lead the development of schools as personal and professional learning communities, building relationships across and beyond each school to provide a range of learning experiences and professional development opportunities.
- lead work for equity and inclusion through acting on context and culture, not only in response to poverty but also to employ educational resources to help give communities a greater sense of aspiration and empowerment.
- manage strategically the impact of the classroom, school and system on one another, understanding that in order to change the larger system one has to both engage with it in a meaningful way and manage subsequent change at a school level.

This set of five purposes or goals make a powerful case for system leadership. Taken as a whole, they address most of the issues or problems identified with the challenges introduced in the earlier section on defining system leadership.

It is a compelling proposition that such leadership holds significant potential to contribute to systemic educational improvement. It is an idea that was positively advocated by Government Ministers. David Miliband MP, for example, when Minister of State for School Standards, saw that the development and deployment of cadre of system leaders could go a long way to responding to the key challenges he had identified for school leadership as part of a new relationship between schools and Government ([Miliband, 2004](#)). This included raising productivity in education, effecting greater social justice and ensuring sustainable improvement ([DfES, 2005](#); [Miliband, 2003](#)).

Further research identified a variety of system leader roles emerging in England and elsewhere ([Higham et al., 2009](#)). As it happens this taxonomy has received support from subsequent research as seen in Part 2 of this chapter. The role of the National Leader of Education (NLE) has developed considerably in response to these policy suggestions ([Matthews, 2008](#)); as has the concept of the system leader in a more global context ([Hargreaves, 2012](#)). The initial framework suggested the following roles ([Hopkins and Higham, 2007](#)):

- Developing and *leading a successful educational improvement partnership* between several schools, often focused on a set of specific themes that have significant and clear outcomes that reach beyond the capacity of any one single institution.
- Choosing to *lead and improve a school in extremely challenging circumstances* and change local contexts by building and sustaining a culture of success as a high valued added institution.
- *Partnering another school facing difficulties and improve it*, either as an Executive Head Principal of a Federation or as the leader of a more informal improvement arrangement.
- Acting as a *community leader* to broker and shape partnerships and/or networks of wider relationships across local communities to support children's welfare and potential, often through multi agency work.
- Working as a *change agent* or expert leader within the system, identifying best classroom practice and transferring it to support improvement in other's schools.

No doubt these roles will expand and mature over time. What is particularly interesting about them is how they have evolved in the recent past as a response to the adaptive challenge of system change. It is also important to note that the taxonomy includes system leaders working in either national or state programs as well as locally organised often *ad hoc* roles, a point that is picked up again below.

The underlying assumption of this chapter is that the real prize and potential of system leadership is the realisation of systemic improvement. It is important to appreciate a further insight that the aspiration of system transformation can be facilitated by the degree of segmentation existing in the system. Segmentation implies using the natural variation in school performance within the system as a means of improvement through collaboration ([Hopkins, 2007](#)).

There are two crucial aspects here. First, that there is increased clarity on the nature of intervention and support for schools at each phase of the performance cycle. Second, that schools at each phase are clear as to the most productive ways in which to collaborate in order to capitalise on the diversity within system. A summary of this 'segmentation' approach is set out in [Table 1](#).

In the left-hand column is a basic taxonomy of secondary schools in England produced by the DfES in the mid 2000s based on their phase in the performance cycle. It is this that is the focus of the second column, where a range of strategies for supporting schools at different phases of their development are briefly described.

The key point to consider is that these different forms of intervention and support are increasingly being provided by schools themselves, rather than being imposed and delivered by some external agency. This approach to system transformation relies fundamentally on school-to-school support as the basis of the improvement strategy.

Table 1 The ‘segmentation approach’ to school improvement.

<i>Type of school</i>	<i>Key strategies – responsive to context and need</i>
Leading Schools	Become leading practitioners
Succeeding, self-improving schools	Formal federation with lower-performing schools Regular local networking for school leaders Between-school curriculum development
Succeeding schools with internal variations	Consistency interventions: Such as assessment for learning Subject specialist support to particular curriculum areas
Underperforming schools	Linked school support for underperforming departments/year groups Underperforming pupil programs for catch-up
Low attaining schools	Formal support in Federation structure Consultancy in core subjects and best practice
Failing schools	Intensive support from system leader or Restart with new name and leadership

In this section of the chapter, the skills and potential roles of system leaders have been described as well as their strategic contribution to systemic improvement. This of course has been based in the English context, but the overall strategic approach is generic and can apply in a range of settings and jurisdictions. The skills themselves, the range of improvement categories and the terminology associated with intervention will vary from setting to setting and each system will have to develop its own language and framework suited to its own particular purposes and context. The crucial point being that not all schools are the same, each requires different forms of support and at each stage of development there will be a productive re-balancing between prescription and professionalism.

Global perspectives on system leadership pre-2010

In the mid 2000s the OECD launched a major research and development program into School Leadership in participating countries. The program culminated in the publication of two books *Improving School Leadership*, Volume 1: Policy and Practice (Pont et al., 2008a), and *Improving School Leadership*, Volume 2: Case Studies on System Leadership (Pont et al., 2008b). The authors state that throughout OECD countries, there is a great deal of school leadership co-operation and collaboration going on. Practitioners do not work alone, and many benefit from a variety of networking arrangements or new structures that share management across schools. Although the authors were not able to gauge the extent of their success in most countries because they had not pursued the issue systematically, they did say that most initiatives had explicit objectives that concentrated on the following: sharing and rationalising resources, improving coherence of educational provision, supporting wellbeing and improving educational opportunities and outcomes (Pont et al., 2008a).

In fact, in all countries participating in the OECD Improving School Leadership activity, there were some arrangements for co-operation between schools. School leaders were the key to these and are also strongly influenced by them. In order to give a flavor of this activity Table 2 lists different types of approaches and some of the reasons for co-operation across OECD countries.

To summarise, in this first part of the chapter we have discussed some of the theoretical underpinnings of System Leadership, described a framework for explaining its contribution to systemic reform, provided a case study of emerging practice in England, and reviewed briefly the adoption of collaborative ways of working in twelve countries. In Part 2, the discussion moves to a consideration of System leadership post 2010 as the practice begins to achieve maturity and is better embedded in the policy reforms in many countries.

Part two¹

A macro and micro level framework for system leadership

The different interpretations and conceptualisations of system leaders/ship within the international evidence base post 2010 can be separated into *macro* and *micro* level explanations (Harris, 2020). These interpretations sometimes cross-over, making much of the writing on the subject complex to navigate (Boylan, 2016). To make sense of these different interpretations, and the inter-relationships between them, it is helpful to explore system leaders/ship through macro and micro level lenses, respectively. Fig. 2 illustrates the different interpretations and the inter-relationships.

¹Acknowledgment - this section is based upon an unpublished report, on the topic of system leaders and leadership, prepared by one of the authors for the National Academy for Educational Leadership in Wales (Harris, 2020).

Table 2 Different types of approaches to school leader collaboration across OECD countries (Pontet et al., 2008a).

Belgium	- School communities have been created as voluntary collaborative partnerships between schools. They aim to have common staffing, ICT and welfare resources management.
Denmark	- Co-operation in post-compulsory education has been promoted by the creation of administrative groups set up locally or regionally to optimise the joint resources of several self-governing institutions.
Finland	- 2003 legislative reform has enhanced school co-operation aiming to ensure integrity of students' study paths.
France	- "school basins" have been implemented to ensure collaborative partnerships between schools to work together in student orientation, educational coherence between different types of schools, common management of shared material and human resources.
Hungary	- "micro-regional partnerships" based on economic and professional rationalisation have resulted in the spreading of common school maintenance in almost all Hungarian micro regions. This network-type co-operation enables professional and organisational learning leading to new forms of education governance and efficient innovation.
Korea	- small schools cooperate to overcome problems of size in teacher exchange, curriculum organising, joint development activities, and integrated use of facilities.
Netherlands	- In primary education, "upper management" takes management function responsibility for several schools. About 80% of primary school boards have an upper school management bureau for central management, policy staff and support staff.
New Zealand	- school clusters are based around geographical communities and communities of interest.
Norway	- tendency is to merge several schools to form an administrative unit governed by a school principal. Three-level municipalities require networks between schools.
Portugal	- schools are commonly grouped together with a collective management structure; executive, pedagogical and administrative councils are responsible for their areas.
Scotland	- important political promotion of collaboration. "Heads together" is a nationwide online community for sharing leadership experience.
Sweden	- municipal directors of education steer principals. Most of them are members of director of education steering group where strategy, development and results are discussed.
England	- there are different approaches to co-operation stimulated by the government – federations of schools, national leaders of education, school improvement partners ...

**Fig. 2** A Macro and Micro level framework for system leadership.

Macro level

At the macro level, the evidence on system leaders/ship diverges into two major areas of study. Firstly, as was seen earlier, there is a literature on *systems thinking* and *systems theory* that focuses on ways of solving complex problems within and across organisations (e.g. Levin and Schrum, 2013). Secondly, there is a considerable evidence base around system leaders/ship as a policy driver for system change and as the mobilisation of system improvement in different countries and contexts (e.g. Harris et al., 2014; Cousin, 2016; Nasmyth, 2012; Hamilton et al., 2018).

As intimated earlier, systems-thinking, is an approach that is concerned with taking a holistic view of the system. It is a management approach to organisational change that has been applied to schools and connects with closely system science (Shaked and Schechter, 2020). Systems thinking reflects a theoretical orientation on organizational change rather than a practical one. It is viewed as an approach for understanding change within complex systems.

Systems thinking as Fullan (2005) noted places an emphasis upon system thinkers rather than system leaders, reinforcing the capacities of individual leaders within a specific eco-system (Shaked and Schechter, 2014; Toh et al., 2014). Systems thinking is also linked to idea of systemic leadership that appears within the business literature (e.g. Thompson and Zakhirova, 2019) which views organisations as open systems that are visible and inter-connected (Beehner, 2020).

In the second area of study, system leaders/ship is represented and understood as a *policy lever* for school and system improvement. In this respect, system leadership is presented as an adaptive leadership style or disposition that is based on an understanding of the complexity of educational contexts as involving multiple, interrelated systems. System leadership at the macro level focuses on how leadership is exercised for the greater good and how *capacity* is built to deliver system wide change and improvement.

The international literature reflects an extensive evidential base around system leaders/ship as a policy driver for system improvement. In Canada, Finland, Georgia, England, Hong Kong, New York, Latin America, Singapore, Scotland, Australia and New Zealand there are specific examples of policy interventions, around system leader/ship, directly aimed at building the capacity for school/system improvement (Mitchell and Sackney, 2016; Sentocnick et al., 2016; Elwick, 2017; Weinstein and Hernández, 2015; Hamilton et al., 2018; Hopkins 2016; Mowat, 2018; McNaughton et al., 2011; Watterston et al., 2011; Dimmock, 2016; Simon, 2015; Smeds-Nylund et al., 2016; Southworth and Quesnay 2005; Szeto, 2019; Ng, 2017).

System leadership is essentially defined, at the macro level, as having a systemic orientation where system leaders influence those beyond their immediate context and are deliberately deployed to bring about large-scale change. This interpretation has been seen in policy developments in England (Cousin, 2019; Close, 2016) and in many other countries (Pont et al., 2008c).

The implementation of a system model, it has been argued, happens when all stakeholders are active co-collaborators in the modeling of solution seeking processes (Wilkinson, 2016). Within the international evidence base, there are frequent references to system leaders as solution seekers and change agents, as levers for system level change and improvement.

The academic literature similarly reinforces the centrality of system leaders/ship as a macro lever for school and system wide change. For example, Cousin (2018) views system leaders/ship as a public service delivery mechanism within a narrative of global governance. Focusing on England, Cousin (2018) outlines findings from a longitudinal study that demonstrates a positive relationship between system leaders (National Leaders of Education) and school/system improvement. Brown and Greany (2018) also turn their attention to the English education system but offer a more critical view of the evidence about system leaders/ship and its relationship with the self-improving system. Other writers offer examples of system leaders/ship in various settings (e.g. Naicker, 2015; Bryant, 2018; Godfrey, 2017) each reinforcing that system leadership is a macro policy lever and a catalyst for system wide change (Hamilton et al., 2018).

In the macro sense, therefore, system leaders are collectively charged with the development of others and the improvement of the system (Sheppard and Dibbon, 2011; Hopkins et al., 2014) where their sphere of influence varies according to role, responsibility, and level.

Micro level

Moving to the micro-level, re-positions the idea of system leaders/ship away from the collective spheres of influence toward individual functions, roles, traits, or characteristics (Accardi, 2016; Dimmock, 2016). In his work, Hopkins (2009) suggests that system leaders operate at *three levels* –.

1. The level of the school i.e. helping other schools.
2. The local level i.e. working with networks of schools or at the national level.
3. The national/system level i.e. operating as a leader of system change (e.g a National Leader of Education) (Fig. 3).

Fig. 3 The three levels of System Leadership.

Hopkins (2009) further suggests that all these system leader roles are necessary and operate interdependently to secure system level change. This tripartite distinction suggests that system leaders need to understand the micro and macro influences in the system to be most effective. Heifetz and Linsky (2002) suggest that system leaders must exist on ‘the balcony and the dancefloor’. In summary, system leaders not only need to see the bigger picture, but they also need to understand the detail of how to secure change.

The international evidence is replete with accounts of the work of different categories of system leaders e.g. headteacher, principal, district leader, network leader, middle leader or teacher leader (Robinson, 2012; Senge et al., 2015; Cousin, 2019; Boylan, 2016). This evidence base proposes that those occupying existing *leadership roles* within the system are, by default, system leaders with the potential to exercise leadership throughout the system. Simkins et al. (2019) focus on primary heads and argue that through their leadership within the system it is possible to have a vision of a school led system. Spillane et al. (2019) focuses on six school systems in the USA and argues that school leaders are system leaders who affect change and improvement through the processes of sense making.

In their work, Senge et al. (2015) talk about core capabilities for system leader/ship that include the ability to see the needs of the larger system, fostering reflection, building collective engagement, and not being reactive but shaping the future. Earley (2016) similarly offers a series of expectations of system leaders but these tend toward the aspirational rather than the practical.

To summarise, the contemporary evidence base views system leaders/ship as a macro level policy driver and a micro level role or responsibility. The literature reflects three distinctive but interrelated interpretations:

- system leaders/ship *as* system change – e.g. in Singapore, leaders within the system (school, district, and Ministry) collectively operate *as* system change agents (Ng, 2017).
- system leaders/ship *for* system change -e.g. in England, system leaders, (National Leaders of Education) are responsible *for* leading system change (Cousin, 2018)
- system leaders/ship *through* system change - e.g. in Ontario, system change produced literacy co-ordinators and champions who became system leaders *as a direct result of* system wide change (Gallagher et al., 2016)

The next section aims to illuminate these different interpretations further, by offering country specific examples of system leader/leadership.

System leader and system leadership – selected country examples

As seen previously, over a decade ago, the OECD (Pont et al., 2008) highlighted several country cases where system leader/ship was present and prevalent including those summarised here. The short examples that follow (Australia, Singapore, England, and Canada) offer contemporary insights into how system leadership is currently interpreted, understood, and enacted in different contexts. Each of the examples is informed by policy evidence, collected as part of this review, and recent communication with identified country experts.

Australia

To begin with, two experts from Australia offer some important insights into system leaders/leadership in their context:

In Australia, system leadership varies by school type. For government schools, the state or territory Department of Education will have the most system leadership influence and this will have central and regional components. Yet, principals and other school leaders have an equally important role in school success. For Catholic schools, the main system leadership will come from the local diocese. For Independent schools it will vary according to whether they are part of a system or not. As well as this, governance at the school level varies greatly and this will impact on the influence of systems and the work of principals (Gurr, 2020²).

In NSW, the term system leadership, is used to describe the role of senior educators who occupy formal positions that have the responsibility of supporting the effectiveness of schools and school leaders. In NSW, the term system leadership is also used to describe educators who voluntarily undertake roles, with the purpose of contributing to the development of other educators beyond those within their own school. These roles generally include, supporting the professional learning of others as an in-program facilitator, or leading a local network with a focus on an area of educational interest such as curriculum, ICT, or leadership development. Current research regarding in-program facilitators, indicates that the key drivers for educators to undertake these roles include-

- *a commitment to the profession and the well-being of the public education system,*
- *a desire to engage in professional learning through supporting the learning of others,*
- *a desire to network with, and expand their sphere of influence, beyond the school* (McIntyre, 2020³).

Singapore

In Singapore, system leadership is *the* central way that all system change is delivered. School leaders, at all levels, are prepared from day one to take up responsibilities anywhere in the education system, including the Ministry. The National Institute of Education (NIE) trains all teachers and leaders, throughout the country, to a consistently high standard. It prepares them to develop other leaders at all levels in the system. When a teacher is identified as being capable of a leadership responsibility, the final beneficiary is often another school. When the teacher is ready for a leadership position, they may be identified (by the Ministry of Education) to be posted to another school that needs them more or where a better opportunity for further development is available.

In Singapore, teachers and principals are allocated to their posts by the Ministry, it is not their personal choice. Many capable heads of department, who have been in one school, become vice-principals in another school. Similarly, many capable vice-principals, who have worked extensively in one school, will eventually leave, and lead another school. Many highly effective principals join the district or the Ministry level.

In this way leadership positions and responsibilities are rotated in the system. So, in Singapore, school leaders know that they are developing people for the system, rather than just for one school. This is a system high in trust and collaboration. School leaders also trust the system to provide the human resources the school needs (Ng (2017).

In Singapore, school leaders do not just lead a school. They are called to lead 'nationally'. That means that a school leader belongs to a community of leaders. School leaders care for the whole education system, not just the school each of them is currently leading. They must take a broader view and consider how their decisions in school will affect other schools or even the whole nation. Social capital in Singapore is 'nationalistic'. This is the spirit of competitive collaboration. Centralized decentralization can work because the spirit of competitive collaboration helps to drive improvement while keeping the system united (Ng, 2020⁴).

An update on England

In England, the concept of system leadership continues to mature and the 'self-improving school-led system' (SISS) is now the overarching narrative for education policy. This agenda has encompassed an ensemble of reforms since 2010 including academies, the promotion of multi-academy trusts (MATs), the roll back of local authorities (LAs) from school oversight, and the development of new school-to-school support models, such as Teaching School Alliances (TSAs). The government's rationale for this mix of reforms is, ostensibly, to move control to the frontline by giving greater autonomy to schools. To support the SISS, a tranche of National Leaders of Education (NLE's) currently operates to mobilise change across the system and to act as system leaders for school self-improvement. NLE's tend to be high performing leaders and their teams (e.g. as National Leaders of Education or Teaching Schools) who are designated and deployed to support other schools (Earley and Greany, 2017).

Prior to 2010, there was a broad interpretation of system leadership in England (Hopkins and Higham, 2007). Any school leader who played a role beyond their context could consider themselves as engaging in 'system leadership'. Latterly, however, system leaders are formally designated as NLE's with clear lines of accountability to government. The primary function of the NLEs is to deliver school improvement support on behalf of the Department for Education in England (DfE, 2021). The core purpose of the NLE is to deliver support to underperforming schools, helping them to identify and address areas in need of improvement.

Within England tensions exist, however, within the NLE system leadership role. On the one hand, system leaders (NLEs) are encouraged and expected by government to drive relentless and rapid improvement across multiple schools. On the other hand, they are expected simultaneously to address other 'school-led' policy priorities, such as to expand the numbers of trainees on school-led Initial Teacher Training routes. NLEs are charged with working on behalf of the self-improving system, engaging their peers in building collaborative alliances while operating in a competitive marketplace for school improvement services (Greany, 2018).

Greany and Higham (2018) in *Hierarchy, Markets and Networks* highlighted that NLEs in England were experiencing conflicting and unreasonable demands from central government while being perceived by their peers to be a 'co-opted elite', working as part of the managerial state and accruing a range of personal and organizational benefits as a result. Concerns about the NLE role have also been raised because of the importance placed on the Ofsted 'Outstanding grade' to designate those selected as system leaders.

System leaders all identified benefits from their roles, but there are also a series of challenges, including significant pressure to make short-term improvements in other schools and the fear that their own school might drop in performance as a result of their external work

Greany (2020)⁵.

Ontario, Canada

Since 2007, the Province of Ontario in Canada has successfully embarked on a major reform process, largely but not exclusively focusing on improving literacy and numeracy outcomes for young people, particularly those who are most disadvantaged

⁴Personal Communication.

⁵Personal Communication.

(Campbell, 2020). Ontario's educational reform agenda has concentrated consistently on raising the bar and narrowing the achievement gap and on increasing the rates of high school completion.

An important and prominent part of this reform agenda has been the focus on system leadership across the Province. A by-product of system level reform in Ontario has been the attention paid to building professional capacity and leadership capacity at all levels of the education system (province, district, school, and classroom). A central element of this focus has been developing leaders and leadership practices at all levels of the education system. In this respect, system leadership in Ontario has emerged through large-scale system level change. The following two quotes from *Our Call to Action* (National Academy for Educational Leadership Wales 2019, p.11) offer insights into the role of the system leader in Ontario:

One of the strengths of the system is a comprehensive, well-established Ontario Leadership Framework (OLF) providing valued support for professional learning, into roles as centrally assigned principals and beyond as superintendents. This provides a clear pathway for developing future leaders in the system. Principals and vice-principals are allocated from a central pool to schools by the Toronto Board of Education with the expectation that they remain in one school for approximately five years

Nevertheless, there is a compromise to be made, as the expectation to move schools can affect the well-being of principals. However, principals are well supported in their roles by centrally assigned principals who are all experienced leaders. This leads to a high level of trust and mutual respect, which in turn creates an ethos of support rather than challenge in the system

All the country examples reflect the fact that system leadership within and across educational organisations is still considered important to build the necessary professional capital and professional capacity for improvement. As this review of post 2010 practice has highlighted, there is evidence that when properly deployed, system leadership can be a positive force for system change and transformation.

Part three

Toward the future and a reflection

The substance of the previous two parts of this chapter suggests that the concept of system leadership is an idea whose time has come. One can characterise contemporary practice by saying that system leadership is increasingly being seen as:

- A wider resource for school improvement, making more of the most successful school leaders' by encouraging and enabling them to identify and transfer best practice, reduce the risk of innovation in other schools and lead partnerships that improve and diversify educational pathways for students within and across localities.
- A more authentic response to low attaining schools. Strong leadership is vital to turn these schools around. However, a central challenge is that these schools are often the least able to attract suitable leaders. The most successful heads hold the potential to impact on these schools, which need their expertise, by working to develop and mobilize leadership capacity in the pursuit of whole school improvement.
- A potential means to resolve, in the longer term, the emerging and related challenges of a declining demographic supply of well-qualified school leaders, falling student rolls and hence increasingly non-viable schools, and yet ongoing pressures to sustain educational provision in all localities. The evidence cited here suggests that system leadership solutions may include fewer head teachers across some groups of schools, new challenges and incentives for the retention of the most experienced head teachers, as well as new development opportunities for deputies and middle leaders to experience aspects of headship at first hand before taking on full head teacher responsibilities.

Before we get too carried away with such enthusiasm for the concept of system leadership, however, we need to admit that much of the well-intentioned advocacy is based on aspiration and individual cases rather than systemic evidence. Despite its attractiveness as a new catalyst for system change there are a range of challenges to be faced up to if we are to avoid a simplified and uncritical approach to system leadership. We have several concerns:

- First, there is currently no clear or systemic knowledge of how leaders undertake system leadership roles.
- Second, there is insufficient evidence of effectiveness including on the proportion of system leaders who are successful, their impact in different contexts and what might constitute best practice.
- Third, there is no certainty that sufficient leadership quality and crucially whole school capacity already exists to provide a platform on which to develop a wide range of effective and sustainable system leadership roles.
- Fourth, it is not always clear how capacity is renewed within the schools from which system leaders work, especially those in challenging circumstances.
- Fifth, there is no consensus about how best (or who is best placed) to deploy and develop a range of existing and aspirant system leaders to ensure that they gain the skills, experience and support needed to be effective.

- And sixth, there is a wider debate within the head teacher profession about how to reconcile on the one hand an impetus for collaboration between schools with on the other hand an accountability system focused on individual schools (which has the potential to act as an impetus for competition). This perceived tension certainly does not circumscribe nascent system leadership, but it is an important contextual dimension when wider systemic roles are being considered or developed.

In reflecting on these concerns however, there is an overarching challenge to face. It is the distinction between system leaders working in Governmental or State programmes and those working in locally organised often *ad hoc* roles.

As seen in **Part Two**, the majority of system leaders increasingly operate in Governmental or Regional programs that have incentivised activity through organisation, funding and professional development - this is the 'enabling state' at work. It is an important strategy for encouraging Heads and Principals to lead technical and adaptive solutions in a widening professional domain of cross-school and system improvement. It is a phenomenon that is increasingly being seen in those school systems that are accelerating up the PISA international benchmarking scales.

More freedom exists on the other side of the divide, in the roles that are locally developed, often *ad hoc* and contextually responsive. It is understandable why many conceive of these roles to be a more authentic form of system leadership. With no single framework or protocol, a range of models are developed in relation to specific needs and times. Furthermore, from this perspective, the role of an 'enabling state' becomes focused on reducing both barriers to collaboration and wider policy disincentives at all levels. On the other hand, it encourages agencies to provide specific support in networking and bespoke professional development to individual system leaders.

There are of course variations to this bottom up/top-down distinction that are beyond the scope of this chapter and will be dependent on a range of criteria. If, however, a shared criterion is to develop effective system leadership in a growing number of schools, then the following suggestions for action may prove instructive.

Suggestion One: Incentivise rather than legislate. The traditional response has been intervention and management from Governmental, State and Federal Agencies. The argument here is that this leadership now needs to come more from Heads and Principals themselves or from agencies committed to working with them in authentic ways. It is clear that the more bureaucratic the response, the less likely it will be to work. A more lateral approach may be to create the conditions within the system to promote system leadership and collaborative activity through for example, adjusting accountability requirements, and funding for capacity building. With the right incentives in place schools will naturally move toward these new ways of working and mold them to the context in which they operate and to the challenges they face.

Suggestion Two: Place the agency close to the school. There are now in many systems, system leadership roles whose remit is specifically school improvement. The intention that must be maintained is that instead of creating a new bureaucracy, their brief is increasingly focused on facilitating relationships between schools to maximise the potential of purposive collaboration. This approach to school transformation is made increasingly possible by the range of sophisticated data potentially available on school and student performance. It enables groups of schools to identify (a) issues where they shared both strengths and weaknesses i.e. their capacity for sharing, and (b) common issues where they are likely to need some external input.

Suggestion Three: Use school 'independence' collaboratively to tackle underperformance. The underlying assumption here is that autonomous schools working collaboratively is a particularly appropriate organisational format for contexts where rapid transformation of standards and support for students are most needed. The key point is that the freedoms associated with increased autonomy can be used to promote collaboration and inclusion to directly address the needs of students. The crucial condition is that all schools accept responsibility for the education of all the students within their geographic area.

The purpose of this chapter has been to demonstrate that system leadership represents a powerful combination of practices that give us a glimpse of the crucial importance of leadership in the new educational landscape. The collective sharing of skills, expertise and experience creates much richer and more sustainable opportunities for rigorous transformation than can ever be provided by isolated institutions. Realising this landscape, however, may also require a bigger shift within the broader education system, in particular, by giving school leaders more agency to take the lead – in short to light their own fires. The future is certainly theirs.

Introduction

"If it isn't ethical, it isn't leadership" was the title of the final chapter I wrote for the *Handbook of Ethical Educational Leadership* that I co-edited with Steven Gross (Branson and Gross, 2014). Here the term, ethical, implies that a leader's actions are founded upon recognisable principles or values that automatically embrace the common good. Essentially, this particular chapter challenged the widely held view that a person appointed to a position in which they are labeled a leader has the sole right to choose how they will lead. In the opinion of such individuals, leadership is incorrectly assumed to be any activity performed by a person in a leadership position. As a result, the world has witnessed brutally inhumane actions being justified or given credibility by being labeled as leadership practices by persons in influential positions. Arguably however, the wide-ranging influence of Burns' (1978) seminal and Pulitzer Prize-winning text, *Leadership*, in which he described the concept of transformational leadership, as distinct from transactional leadership, initiated a challenge to this potentially precarious autocratic perspective.

According to Burns (1978), the previous leadership theories were essentially transactional in nature because they afforded total control to the person in the leadership position. Such transactional leadership theories concentrated almost solely on what the leader had to do or provide to those they were supposedly leading in exchange for their loyalty and commitment toward maximizing their work quality and individual output so as to continually benefit the organisation's purpose. In contrast, Burns argued that leadership practice would be better served if it concentrated on transforming those being led. In order to transform the people, the leader should not only concentrate on making those being led more knowledgeable and skillful about their work but also that their work would become more meaningful. Burns' view is that once the person feels capable in doing work that is more meaningful to them, they will naturally perform their work more efficiently and effectively. Essentially, the application of a transformational approach to leadership introduced the need for the person in the leadership position to be far more considerate and inclusive of the needs of those being led.

Important within this discussion of the essential role of ethical practice in leadership is Burns' (1978) argument that a fundamental requirement in leadership is that

leaders address themselves to followers wants, needs, and other motivations, as well as their own, and thus they serve as an independent force in changing the make up of the followers' motive base through gratifying their motives (p. 20, italics in original text).

Later he urges "leaders must accommodate followers wants and needs without sacrificing basic principles" (p. 77) so that they can "help transform followers' needs into positive hopes and aspirations" (p. 117). Finally, in a very powerful manner, Burns warns that the

test of leadership in all its forms is the realization of purpose measured by popular needs manifested in social and human values. Leaders can operate off the “skin” of public opinion - off surges of trending opinion, the applause of idolizing spectators, the bubbling up of passing social and political fads, trumped up foreign crises, and exaggerated dangers to national security - without recognizing the persisting, widespread, and intensive needs and goals that motivate followers and are there for the evoking by leaders (p. 251).

The challenge for the leader, according to Burns, is not to be moved and influenced by the superficial, generalist, presumed values and needs of the followers but those that are at the very core of their thoughts, feelings and actions. Simply stated, this is a view of leadership whereby the needs of those being led, and not the leader's or the organization's interests, is the primary departure point for the leader's actions, which is the cornerstone of ethical leadership practice. This understanding is pivotal in denouncing the claims to leadership by those in positions of high office who use charismatic appeal or misleading information to manipulate the emotions and beliefs of others for their own self-interests.

Subsequent leadership theories have followed Burn's lead of adding an ethical expectation to leadership practice. For example, [Hodgkinson \(1978\)](#) called for the restoration of a moral foundation of theories on educational leadership. A few years later, [Greenfield \(1981\)](#) and [Foster \(1986\)](#) emphasized the need for further study into the ethical and moral aspects of educational leadership. [Begley \(2003\)](#) described the concept of authentic leadership as a “professionally effective, ethically sound, and consciously reflective” (p. 1) form of leadership. Also, when promoting moral leadership, both [Sergiovanni \(1992\)](#) and [Starratt \(1994\)](#) shared the view that the leader must closely consider what is significant, what is right and what is worthwhile in all of their decision-making activities and that commitment to such ethical and moral behavior elevates the leader above mere pragmatics or expediency so as to raise their moral reasoning in order to transform their self and those they lead. Also, [Day \(2000\)](#) argued that the fulfillment of a truly transformational approach to leadership was depended upon a far more “values-led” commitment than initially considered due to the ever-increasing influence of change and uncertainty upon the role of the leader. Thus, a substantial and growing body of research ensued aimed at developing an understanding regarding the ethical dimensions of leadership in schools ([Arar et al., 2016](#); [Langlois et al., 2014](#)).

However, despite more than 40 years of literature describing and promoting the ethical imperative in educational leadership, it is yet to gain profound understanding and therefore universal traction. Hence, this chapter seeks to overcome this deficiency in three ways. First, it will outline the diverse and compelling reasons for why 21st Century educational leadership must be unequivocally founded upon an ethical base. Then this chapter will briefly review the expansive ethical leadership literature in order to not only show what has been proposed to date regarding the practice of ethical educational leadership but also to highlight its apparent insufficiency. Finally, this chapter will describe how this insufficiency can be overcome and thereby providing an explanation for why true leadership is intrinsically ethical. The fundamental message of this chapter is that educational leadership is not about becoming an ethical leader but rather it is about becoming a leader in the true sense of the word because this demands a commitment to being ethical.

Why ethical educational leadership?

Clearly the 2008 global financial crisis brought the concept of ethical leadership into the international spotlight. The worldwide physical, financial and psychological devastation caused by the unethical practices of a relatively few individuals and institutions within the banking and investment world drew universal attention to the need for ethical leadership practices. However, in reality this incident was only one of an ever-growing number of very serious unethical activities by people in leadership positions in the political, industrial, religious, media, and education spheres. Within the political sphere there have been a growing number of coalition governments as voters became disillusioned and skeptical about whom to support as decisions by politicians regardless of persuasion appear to be founded on self-interest rather than common good reasons. In the industrial scene, decisions by those in leadership positions being based upon economic benefit rather than human safety were behind the catastrophic oil pollution incident in the Gulf of Mexico and the mining disaster in New Zealand that led to the death of 39 miners. Individuals in religious leadership positions have acted contrary to their religious principles and norms by becoming civil militia leaders in Ireland, the Middle East and North Africa or have concealed criminal behavior by some of their ministers. England witnessed phone hacking by media employees in leadership positions who were desperate to boost sales. Also, persons in educational leadership positions have been found to have acted fraudulently when overseeing formal student assessment procedures while others have misappropriated their institution's financial and/or physical resources.

As a result of seemingly burgeoning occurrences of unethical practices by people in leadership positions, having a commitment to being ethical is now being viewed as an inviolable expectation of leaders. It is expected that our leaders will act morally whereby they will not produce harm but rather will show the virtues of doing good, of honoring others, of taking positive stands, and of behaving in ways that clearly show that their own self-interests are not the driving motivation behind their actions ([Branson, 2014a](#)). People want to know that their leaders are there for them; that the leader is one of them. People will only fully support leaders who act fairly, justly and promote good rather than harm. They want their leaders to be accountable to them in what they do just as they accept they will be accountable to the leader and others in what they do. More so than ever before, people will only respect leaders who are ethical whereby they are guided by “an internal moral compass that directs them to take on tasks,

assume styles, and behave commensurate with organisational beliefs regarding right and wrong, virtue and vice, and social responsibility" (Normore and Doscher, 2007, p. 2).

In conjunction with this call for ethical leadership arising from a general concern about the prevalence of unethical leadership there now exists a very clear realization of its importance in maintaining global economic stability as our world transitions from the third to the fourth stage of the industrial revolution (Industry 4.0). From an Industry 3.0 world influenced by electronics, computers and automated manufacturing to one that will be influenced by cyber-physical systems in which real objects and virtual processes are interlinked. But getting to this fourth stage is not solely dependent upon technological developments because particular socio-cultural changes will be required, too. As artificial intelligence, the internet-of-things, and machine learning replace people in most routine and repetitive type tasks, it will be essential for leaders to be ever mindful of protecting working conditions, of helping to shape the extent of automation as applied to jobs, and of preventing the digital revolution from widening inequalities. Simply stated, as the world moves toward Industry 4.0 the perspective of leaders must switch from "could we" to "should we" (Deloitte, 2020), which implies a mandatory commitment to ethical decision-making. As the 2020 Deloitte *Global Human Capital Trends Report* argues, "how organizations combine people and machines, govern new human-machine work combinations, and operationalize the working relationship between humans, teams, and machines will be at the center of how ethical concerns can be managed for the broadest range of benefits." (p. 98).

For the educational leader, the growing general demand for ethical leadership in conjunction with this Industry 4.0 perspective adds considerable import for ethical educational leadership. Certainly, the need for educational leaders to abide by legal obligations and proper fiscal practices is unequivocal and it is only on very few occasions that individual principals have not met this mandatory expectation. But, as more and more are being asked of the educational leaders, choosing what to attend to and what to put off or overlook is an ethical decision. Each person can be influenced by personal preferences and our mind is very adept at defending these perspectives. Thus, any choice by an educational leader about where to concentrate her/his interests and energy must be based on common good and not self-interest – it must be an ethical choice and not for personal benefit.

Also, the learning environment within an educational setting must be in the best interests of each student's future and not what maintains, necessarily, the professional and personal interests and comfort of the teachers. This means that change is a constant companion for everyone working in an educational organization. However, we all know that leading change, which begins in the role of the leader, is fraught with difficult challenges. But to ignore the future needs of the students, or to ignore the need to change because of its challenges, are unethical leadership decisions.

Into these ethical dilemmas for the educational leader add issues associated with the need for an authentic commitment to properly attending to cultural needs, family needs, and local community needs within the educational setting. Also, there is the need by the educational leader to lead their educational community to appropriately respond to political initiatives that may or may not benefit the students and the school. Not least, of course, is the need for the educational leader to ensure they make proper choices about their own life balance whereby neither work nor family/leisure gain an inappropriate hold or prominence on their lifestyle.

Every choice an educational leader makes is based on values that are either known or unknown, acknowledged or unacknowledged, by them. The less known or acknowledged are the values that direct a choice, the more likely that an unethical decision will be made, particularly in very unusual, complex and challenging situations. More and more today, educational leaders are being regularly confronted by unusual, complex and challenging situations, which demand them to make a choice. Indeed, ethical leadership is part and parcel of educational leadership, today. Perhaps the most important choice that an educational leader has to make is in answer to the question – Do I want to be an ethical educational leader?

But, before looking at what is promoted as proper ethical educational leadership practice, it is important to, first, establish a common understanding of what constitutes ethical leadership.

Ethical leadership defined

According to the widely supported view of Brown et al. (2005), ethical leadership can be defined as "the demonstration of normatively appropriate conduct through personal actions and interpersonal relationships, and the promotion of such conduct to followers through two-way communication, reinforcement, and decision-making" (p. 120). The first part of this definition relates to the *ethical person* responsibility of ethical leadership and the second part to the *ethical developer* responsibility. Leaders embracing the ethical person perspective strive to be a role model for what constitutes an ethical person through their integrity, honesty, fairness, trustworthiness, and care for the well-being of others. The ethical developer proactively advocates and engenders ethical behaviors in others through their efforts to influence and guide the ethical behavior of those they are leading by regularly communicating and explaining ethical standards, acknowledging and affirming those who act ethically, and suitably disciplining employees who demonstrate unethical behaviors.

In regard to what ethical leadership might imply in an educational context, Nancy Tuana (2014) provides a very similar view to that of Brown and colleagues when arguing that "effective and responsible educational leaders must also be ethical leaders [whereby] their leadership decisions and practices be based on ethical values and principles [and] that they lead with ethics in the sense of being committed to, and take a leadership role, in ensuring the development of moral literacy throughout their communities" (p. 262). She goes on to argue that effective ethical educational leadership is grounded on the recognition that ethical leadership mandates putting ethics in the foreground of all activities. It is not possible for the actions of only one person, no matter how ethical or how effective a leader, to make an entire community ethical. An ethical community exists because the commitment to

ethical leadership permeates the entire community. Hence, the focus on ethical leadership cannot be solely limited to the practises of the school leader as the ultimate aim must surely be about educating the entire school community to act ethically. So, what might this mean in practice?

Ethical educational leadership practice

Although there is a substantial pool of resources available for those wishing to develop ethical educational leadership practices, these resources mostly concentrate on the *ethical developer* perspective, particularly ethical decision-making. This is because these resources treat being ethical more like a recipe than a manifestation of the leader's character. The inherent assumption here is that all the leader requires for being ethical is to be seen as acting ethically according to a prescribed process. Moreover, the critically important time for the leader to be seen as ethical is presumed to be in their decision-making. Arguably, this concentration upon ensuring that a leader's decision-making process is ethical is founded upon the realization that, in today's far less predictable, controllable and uniform world, leaders can no longer depend upon past solutions when solving current problems that often contain value contestations or ethical dilemmas. Ethical dilemmas are ill-defined problems that have high-stakes consequences. Navigating ethical dilemmas requires recognition and proper representation of multiple pieces of information. It also requires intuitive judgment about potential outcomes. Ethical decision making is about the leader doing what they ought to do for the good of all rather than just doing what they would like to do. Thus, the aim of ethical decision-making is to ensure that the leader's conscious or unconscious interests and preferences to not undermine the process so that it remains just, fair, thorough and defensible. Thus, for a leader's decision to be ethical the process must be seen to be inclusive of all necessary information, be free from the leader's self-interests, be generally applicable, and be trustworthy in producing understandable and explainable outcomes.

To this end, there are three different types of approaches to ethical decision-making. First, there is the simple logical-sequential approach whereby the author proposes an ordered series of steps for the leader to follow toward the achievement of an ethical decision. For example, the Markkula Center for Applied Ethics at Santa Clara University suggests the following five steps when making an ethical decision: Recognize an ethical issue; Get the facts; Evaluate alternative actions; Make a decision and test it; Act and reflect on the outcomes. This resource, like others that are similar, provides further clarifying questions and/or statements to be addressed within each step. A Google search of ethical decision-making models returns more than 200 million sites. Many of these sites provide a similar version of this logical-sequential approach. Although such an approach provides clarity of purpose during a time of ambiguity and uncertainty its significant limitation is in its assumption that the leader has the capacity to know how to recognize the presence of an ethical issue and to be able to suspend unconscious biases or ignorance when getting the facts and evaluating alternative actions.

An alternative approach to ethical decision-making strives to overcome these limitations by providing a far more holistic process often presented as a flowchart or model. For example, the ethical decision-making model proposed by [Cranston et al. \(2014, p. 237\)](#) provides the following nine lenses the leader can use to ensure they "get the facts" about the ethical dilemma; professional ethics, organisational culture, public interest, global context, economic and financial context, legal issues and policies, institutional context, society, and political framework. In addition, these authors acknowledge the potential influence of the leader's unconscious biases and propose that the leader should consult with a "significant other" (p. 238) in order to nullify any such limitation on the choices and judgements. A somewhat similar model is the *Leader Sensemaking Model* posited by [Thiel et al. \(2012\)](#). The uniqueness of this particular model is the view that, for most leaders, "ethical awareness is grossly misunderstood and under simplified" (p. 49). Hence, the inclusion of a sensemaking component in the model whereby sensemaking is defined as "the complex cognitive process engaged in when one is faced with complex and high-risk situations" (p. 50). Although this approach strives to comprehensively illustrate the decision-making process in order to offer a far more prescriptive procedure, it is precisely this characteristic that produces its limitation. Such an approach can appear as being far too cumbersome with too many issues to consider making the process even more complex and obscure.

The third approach to ethical decision-making is based on a philosophical rather than a logical sequential foundation. The research of [Shapiro and Stefkovich \(2016\)](#) illustrates this approach; their text describing the approach has been published in many different languages and is used widely around the world. Instead of a sequence of steps to follow, this approach guides the leader toward applying the four paradigms of the ethics of justice, critique, care, and the profession when gathering the facts and making a decision in regard to an ethical dilemma. The ethic of justice directs the leader's attention toward determining which laws, rights, and policies need to be considered. The ethic of critique stands in opposition to that of justice by requiring the leader to review any inherent problems, inequities, or deficiencies within the information gathered via the ethic of justice. The ethic of care calls upon the leader to listen to others, to be concerned for the well-being of all, and to attend to the needs of all affected by the outcomes generated by the decision-making process. Finally, the ethic of the profession recognizes that those who work in education must personify the highest moral ideals of the profession by presenting an ideal image of the moral character of both the profession and the professional. It is argued that the leader is far more able to arrive at an ethically authentic and defensible decision if they are able to sincerely and comprehensively apply each of these paradigms to a complex ethical dilemma. From the diverse information gathered by applying each of these paradigms, the leader will be more able to determine the best, the most ethically appropriate, decision.

However, despite the abundance and diversity of advice to leaders, particularly educational leaders, over the past 25 years on how to implement an ethical decision-making process it would seem that little progress has been made. The issue persists not

only in the negative form of unethical leadership behavior but also, and arguably more concerning, in the form of ongoing leadership doubt and uncertainty about how to confidently enact ethical decision-making processes. This suggests that, despite all our efforts to the contrary, there must be some factor that is often missing from each of these different approaches to ethical decision-making.

Why is the issue persisting?

The genesis of this missing factor is captured in [Nancy Tuana's \(2014\)](#) view that there is more to ethical leadership than simply ethical reasoning as encompassed in each of the aforementioned approaches to ethical decision-making. According to Tuana, leaders also require moral literacy whereby they must gain the essential skills and abilities to become moral agents. As a moral agent not only must "their leadership decisions and practices be based on ethical values and principles, but also that they 'lead with ethics' in the sense of being committed to, and taking a leadership role in, ensuring the development of moral literacy throughout their school community" (2014, p. 153). Moreover, Tuana posits that such moral literacy consists of the following three elements: Ethical sensitivity, Ethical decision-making skills, and Ethical motivation.

The first element, ethical sensitivity, is defined as consisting of three major components: 1. The ability to determine whether or not a situation involves ethical issues; 2. The ability to identify the moral virtues or values underlying an ethical issue; and 3. Awareness of the moral intensity of the ethical issue. The second element, ethical decision-making skills has already been well addressed in the previous section. Indeed, there is so much available literature describing different versions of the three ethical decision-making approaches described above because it has been mistakenly assumed that this is all that a leader required in order to enact ethical leadership. But, if the leader is not ethically sensitive, then any knowledge about ethical decision-making processes is likely to be rarely or inappropriately applied. However, even with sensitivity and process knowledge and skills, a leader is prone to avoiding making an ethical decision unless they are absolutely committed to doing so. In the heat of the moment, when there are heightened emotions and calls for quick action due to the seriousness of the situation, the tendency has been that leaders most often revert to past actions and quick fixes. Ethical processes are intentionally or unintentionally forgotten. In such circumstances, it takes the undeterred and wholehearted commitment by the leader to ensure ethical procedures are thoroughly adopted despite the pressures from many sources for this not to be the case. Sadly, research shows that, for many educational leaders, the desire to be ethical when combined with a strong predisposition for individual gain tends to produce moral masquerading ([Branson, 2014b](#)). This research suggests that many educational leaders are motivated more toward appearing ethical rather than actually being ethical. Moreover, it highlights the importance of exploring the concept of ethical motivation as a precursor to the successful development of ethical leadership practice. Without ethical motivation, ethical educational leadership is likely to remain more of an ideal than a regular reality.

While much has already been done to help leaders understand what constitutes ethical leadership and how to implement ethical decision-making practices, little has been directed toward exploring the nature and practice of ethical motivation. To this end, however, [Branson \(2014b\)](#) argues that ethical motivation is about instinctively and consistently doing what is right for the good of others in the absence of incentives or sanctions. This is the highest form of human motivation as it is founded, not on the leader's own physical needs or personal gains but, rather, on intersubjective relationships, interpersonal friendships, mutual appreciation, and a feeling of belonging with and for others. This level of motivation has been variously referred to as an innate desire to fulfill potentialities ([May, 1967](#)), to achieve self-actualization ([Maslow, 1968](#)), to reach for self-completion ([Hultman and Gellermann, 2002](#)), or to attain self-enhancement ([Osborne, 1996](#)). Furthermore, it is noted that people pursue this motive for personal betterment or self-enhancement through two secondary motives ([Branson, 2014b](#)). Firstly, people seek self-enhancement through the motive to achieve success, which focuses on competence. Secondly, people seek self-enhancement through the motive to do things properly, which focuses on integrity. To have worth, people must believe that they are both competent and have integrity in what they are doing and in what others see them doing. People are motivated to do things that not only show to their selves that they are competent and have integrity but also so that they can believe that others share this same positive view of them. This suggests that competence and integrity have both a personal and a social dimension. In other words, the fundamental human motive for self-enhancement causes people to strive toward personal and social competence as well as striving to have personal and social integrity.

However, this perspective requires some further development to make it more specific to the role of an educational leader. It is argued that educational leaders are not only motivated to do things that show to their selves and others that they are competent and have integrity but also that show expected leadership qualities within their educational organization. Leadership does not happen in a vacuum; leadership occurs within a particular designated social group or organization. Also, the credibility within the leader's own eyes, and the eyes of others, is very dependent upon the leader's performance in enabling the organization to achieve a meaningful and successful outcome. This means that not only is the organizational context a source of motivation for the leader but also the leader strives to display expected leadership behavior. Within our current leadership literature, such outcomes are described as the leader's pursuit of authenticity. Authenticity implies a genuine, personal kind of leadership that is hopeful, open-ended, visionary, and creative ([Gardner et al., 2005](#)). In addition, leadership based on authenticity has a social dimension, as it is described as being sophisticated, knowledge based, and skillful in its response to the social demands of people having to work together ([Begley, 2006](#)). Being authentic means that the leader is able to acknowledge and accommodate in an integrative way the legitimate needs of individuals, groups, organizations, communities, and cultures rather than being only concerned by the organizational perspectives that have been the usual preoccupation of much of the leadership literature.

In summary, then, this discussion argues that the fundamental human motive for personal betterment or self-enhancement causes an ethical educational leader to strive toward displaying:

- Personal, social, and organizational competence
- Personal, social, and organizational integrity
- Personal, social, and organizational authenticity

Based upon this understanding of the importance of the fundamental human motive for personal betterment or self-enhancement, the following personal characteristics matrix is used to further clarify and describe the values that can be nurtured as a means of intentionally developing ethical leadership practices (Table 1).

This matrix of values suggests that the development of ethical leadership can be more readily accomplished by encouraging and supporting the educational leaders' growth in applying the values of self-knowledge, connectedness, transcendence, ethicalness, trustworthiness, responsibility, autonomy, presence, and wise judgment in guiding all of their leadership activities. A brief outline of each of these values follows.

Personal competence (self-knowledge)

Self-knowledge is about educational leaders having the capacity and commitment to use self-reflection to form an accurate, veridical model of their selves and to be able to use this unique source of knowledge to operate more effectively in their role as a leader (Bran-son, 2009). Such self-knowledge enables the educational leader to clarify their thinking, raise their self-awareness, develop their relationships on an intimate level, and get in touch with their emotions, thus unleashing their intuition and putting their selves in immediate contact with the school and its community. Such leaders have the courage and commitment to work with the reality of their thoughts, feelings, and environment, going at their own pace on a journey of self-discovery, developing their inner selves, growing in their courage to make ethical decisions, and building supportive and sustainable relationships.

Social competence (connectedness)

Connectedness in ethical leadership promotes the belief that it is imperative for today's educational leader to know that, given their own bounded rationality, discussion, dialogue, and soliciting divergent points of view is the only way to develop better solutions to ethical problems (Berkovich, 2018). This acknowledges that no single person alone is likely to have the combined knowledge and capacities necessary to reach the most appropriate ethical decision. Furthermore, connectedness in leadership acknowledges that contemporary educational leaders need to be more sensitive and caring in their attitudes and relationships. Connected educational leaders transcend the ordinary level of social relations by listening to the burdens of others, caring for them, and putting their selves in the place of others. In this way, the connected leader is able to consider the impact of the ethical issue and the chosen response on all affected by it, and to provide the appropriate support accordingly.

Organisational competence (transcendence)

Transcendence in leadership means that the educational leader has moved beyond, or transcended, their personal ordinary self-interested or self-centred ways. Transcended leaders realize that there are far more important considerations than those that focus on their self and that their leadership role is not about what is right for them, but about the things that are important to the people and the educational organization that they are leading (Starratt, 2004). Moreover, the transcended leader's life is about knowing the right things to do and doing them well. They can see the bigger picture and are willing to become a part of the school community that is striving to make this a reality. Those being led can see and follow the leader's ethical dedication, commitment, and convictions, can discern and appreciate the leader's values and motives, and can be inspired by the leader's sense of purpose and sincerity. An important part of such a leader is in their ability to model ethical values, beliefs, and behaviors. Through their transcended approach, ethical educational leaders become capable of inspiring others by their truthfulness and virtuousness in what they say and do, and in the honesty and transparency in the way they make clear the ethical reasons upon which their decisions are made.

Table 1 A matrix of values for sustaining the self-enhancement motivation, which is fundamental in the development of ethical educational leadership.

		<i>Context</i>		
		<i>Personal</i>	<i>Social</i>	<i>Organizational</i>
Desired outcome	Competence	Self-knowledge	Connectedness	Transcendence
	Integrity	Ethicalness	Trustworthiness	Responsibility
	Authenticity	Autonomy	Presence	Wise-judgment

Personal integrity (ethicalness)

It is not enough for educational leaders just to make the right moves for any purpose that suits them or for any vision that they might have of what their educational organizations should be like — they must consider carefully the impact of all they do on the livelihood of others (Badaracco, 2006). Educational leaders must be fully committed to act ethically such that their purposes and visions are socially useful, serve the common good, meet the needs of their staff, and elevate their staff, students and school community to a higher moral level. This requires them to be a person of courage and integrity, who is passionately committed to doing the right thing regardless of the consequences. Hence, they must continually monitor their own behavior to ensure that it is being influenced by the right values. This commitment to an ethical approach acknowledges that an essential responsibility of educational leadership is in influencing all within their school community to act ethically.

Social integrity (trustworthiness)

People need to be able to trust their leader. Being trustworthy is about the educational leader willingly acting openly, honestly, ethically and consistently (Walumbwa et al., 2011). It is more than simply telling the truth. Trustworthiness means that the educational leader consistently displays total congruence between who they say they are and what they do. Such congruence builds not only trustworthiness but also acceptance. Trustworthy leaders do not seek to be treated more advantageously than those they lead. They do not seek more from others than they are willing to give of themselves. A truly trustworthy educational leader is seen and accepted by those in their school community as being one of them, someone who is truly a part of the community. This is a leader who willingly and readily lives the community's norms and principles and, more, advocates and champions the benefits to be gained for all who follow suit. Trustworthy leaders are consistent and fair in the way they treat each of their school community members. All are treated equitably, with no one gaining benefit or advantage from the leader through preferential treatment, unacknowledged actions, or exclusive opportunities.

Organisational integrity (responsibility)

Responsibility comes from self-reference and self-organization, compliance comes from regulations and policies; responsibility comes from a conscious commitment to what is meaningful and beneficial not only to one's self but also to others (Cloud, 2009). Educational leaders who willingly embrace their need to show organisational responsibility take ownership of the results achieved by the school community and do not try to make excuses for poor performances or blame someone else for them. They accept that they are accountable for the choices they make and take responsibility for what is happening in the school as well as for their own performance. Responsible educational leaders learn from errors or omissions in judgment regardless of who makes them and, rather than seeing faults, they see opportunities to learn and grow both in themselves and others. Moreover, responsible educational leaders have a deep conviction that they must help create the best learning environment for the students and they devote themselves to making this happen despite obstacles, frustrations, resistances, mistakes, and competing demands. But they do this in a way that shows that they accept their moral responsibility for the welfare of others. The responsible educational leader strives to infuse a morally appropriate school culture in which everyone respects the dignity, integrity, and worth of each of their school community members.

Personal authenticity (autonomy)

Acting with autonomy means invariably using one's freedom to act according to one's own consciousness as informed by the full consideration of one's objective and subjective reasoning. For the ethical educational leader to be acting with autonomy means that they use their informed consciousness and sense of what is right to stave off influences that would prevent them behaving or living in keeping with ethical principles. As such, the leader's autonomy does not depend on external authority; instead, it ultimately depends on how they understand and remain true to their selves. It is the freedom the leader gains by repelling interference, manipulation, temptation, and social pressure. It is the freedom that, though often hard won, is nevertheless there to be won. Furthermore, autonomous leaders are consistently authentic to their selves. They are not expected to copy someone else's way of being a leader. As authentic leaders, they find the style of leadership that brings out the best in them and offers the best help to those they lead. As described by Gardner et al. (2005), authentic leadership extends beyond the authenticity of the leader as a person to encompass authentic relations with followers and colleagues. Having personal autonomy enables the leader to be consistently true to their core beliefs and values, which not only ensures they exhibit authentic behavior but also positively fosters the development of ethical behavior in those being led.

Social authenticity (presence)

Effective educational leadership inherently necessitates an influencing relationship – influencing others to see how they can be continually growing personally and professionally. Here, the concept of “presence” has gained prominence. According to Senge et al. (2007), presence involves being fully conscious and aware in the present moment through deep listening, and of being open beyond one's preconceptions and historical ways of making sense. Being able to consciously feel, understand, analyze,

and employ one's immediate experience is an essential aspect of being present. This involves being present to one's self and being present to the others. Being present to one's self is about thinking differently whereby both objective and subjective data from the immediate experience are brought into awareness and, together, these inform the person's deliberations rather than simply repeating past habitual ways of thinking. While being present to the others does not only mean being there physically and hearing what others have to say but rather it necessitates the need to be there fully for the others. Presence in educational leadership implies that the leader willingly and consistently directs alert attention and empathic sensitivity to each of their school community members whenever necessary so that their presence activates not only their own authenticity but also the authenticity of these others.

Organisational authenticity (wise judgment)

Simpson and French (2006, p. 249) propose that "leadership is evoked precisely in moments or situations where we do not know - either what we are doing, or where we are going, or how to get to where we want to be". To be a leader is to be thrown into ambiguity (Endres et al., 2009) and situations that demand "swift and nimble action" (Ropo and Sauer, 2008, p. 565). Moreover, Lawler (2005, p. 227) concludes that leadership is "inherently a chaotic, irrational, emotional phenomenon" such that Pye (2005, p. 47) argues that leadership is "sensemaking in action." In other words, leadership in general, and ethical leadership in particular, calls for wise judgment in the face of uncertainty, unpredictability, and ethical implications. Thus Sternberg (2007) describes successful and effective leadership as the result of a synthesis of three key attributes — wisdom, intelligence, and creativity. He adds that a successful leader needs creativity to generate good ideas, academic intelligence to ascertain whether the ideas are good, practical intelligence to persuade other people, and wisdom to make the ideas work for the common good. Similarly, Bierly et al. (2000) contend that wisdom relates to the ability to effectively choose and apply appropriate knowledge in a given situation and define wisdom as the ability to best use knowledge to establish and achieve desired goals. Importantly, Small (2004) proposes that wisdom is having the power to apply experience and knowledge critically, ethically, and practically.

Summation - where to from here?

This chapter began by arguing that now more than ever before, it is time to challenge the superficial, erroneous and potentially harmful assumption that any person appointed or elected to a leadership position automatically becomes a leader. It must be acknowledged that a leader who is not deliberately and sincerely striving to be ethical is only simulating, if not fabricating, leadership. The actions of a leader, who is not deliberately and sincerely striving to be ethical, is management, at best, or something far more sinister and deceptive, at worst. It's time to stop calling this "leadership" because this only justifies or gives credibility to such actions. Leading ethically must not remain optional but rather become an imperative for anyone wishing to be called a leader especially for an educational leader.

Moreover, there is much more to actually being an ethical educational leader than simply knowing how to make an ethical decision. It is crucial that ethical educational leadership is seen as a personal attribute rather than a professional capability. Knowing how to enact ethical decision-making is insufficient in and of itself. If this were not so, then the growing concern for an apparent lack of ethical educational leadership would not be evident because there has been an abundant amount of literature during the past 30 years describing how leaders can implement ethical decisions. We cannot be satisfied if our educational leaders can demonstrate that they know how to solve theoretical ethical dilemmas or mount a moral argument but struggle to apply such knowledge and capability in their daily work. They need to go beyond *potential* to *habits* of behavior whereby they naturally live out a coherent and defensible values position, *choosing* to apply their ethical knowledge and capabilities daily in a rapidly evolving complex reality. An outside observer should be able to say, not that our educational leaders have a particular ethical capability, but that they live it. Being ethical is a personal attribute that one associates with them. Thus, our focus should be on developing the ethical person, not predominantly on developing their ethical capability.

This implies that the genesis of ethical educational leadership is in the leader's "being" and not just their "doing". It manifests from the educational leader's person, their character, and their behavior is but the tangible reflection of this. Simply having the desire to act ethically does not translate, necessarily, to actually being an ethical educational leader. Ethical educational leadership is an achievement and not a given. A leader has to strive, to be determinedly motivated, to become an authentically ethical person in order to be able to enact ethical leadership. As I argued previously (Branson, 2014b), if we want ethical leaders who naturally act with heart and soul, leaders with courage based on inner ethical strength, wisdom, and grace, if we want leaders with breadth of ethical vision and depth of character, then we will need to support them in developing themselves to their real depths, not by following some decision-making formula, but by supporting them in finding out who they are, what they are made of, who it is that they really want to become, and what values will help them to become this ethical person. If it is possible to help individuals to develop the skills and knowledge necessary to cater for their physical, safety, belonging, and esteem needs, then it must be similarly possible to help educational leaders to develop their skills, knowledge, and character so that they are able to reach their full ethical educational leadership potential.

Introduction

Internationally there have been many calls for schools to be learning organizations and for leadership and teaching policies and practices to be more closely informed by research. For instance, in USA, since 2002, the Institute of Education Sciences has funded over 300 evaluations in schools (Tipton et al., 2021). In Australia, there have been renewed calls for schools and teachers to become research-rich (Shore et al., 2017) and for the school systems to use evidence for improvement (APC) 2016. Similar policy movements can be seen in several other jurisdictions.

This chapter has three overall aims: to describe this field of academic study, to bring the reader up to date with some relevant research and to assess the strength of this scholarship and identify gaps for further exploration. The chapter first describes the parameters used in describing schools as research-informed learning organizations vis a vis the identification of the academic fields that intersect this topic, key concepts, and their definitions. Some of the debates and discussions in this area will also be outlined, including the relationship between academic research and the practices of teaching and school leadership. The intention here is to outline the contested nature of some of the theoretical and normative positions adopted by scholars and researchers in this area, for instance, the notion of *what works* research and of teaching as a research-informed profession. This is important, since resolutions to these arguments result in different outcomes about school organizational configurations, the ways that teachers work with research and the kinds of research used by school leaders to inform decisions.

The author's and others' preferred conception of this area, that is, research-engaged schools, and the (eco)-system perspective on how such institutions serve as lynchpins in a dynamic and improving school system, is then outlined. The chapter then brings the reader up to date with a range of international publications, providing some conclusions from these studies, particularly the leadership conditions and factors involved in promoting research-engagement in schools. This is achieved by analyzing 17 publications from 2017 to 2021 covering a wide range of pertinent foci and empirical evidence from nine countries and examining the issues from all levels of the ecosystem. The chapter ends with a look at the strength of claims made in this academic field, first by looking at research that attempts to link research-engagement with school improvement and secondly by describing systematic reviews in areas highly pertinent to this topic. In summarizing this work, the intention is to gauge current thinking on schools as research-informed organizations. Areas that require more exploration are discussed and further research avenues are proposed to explore gaps and to bolster claims made, including the efficacy of approaches designed to promote research engagement.

The theoretical landscape

As will be discussed further in this chapter, the field concerning schools as research-informed learning organizations covers several overlapping areas of scholarship. A quick reflection on the elements involvement in making practice and policy within schools "research-informed" will make its multi-faceted nature clear; these include, among others: the nature of research-use by teachers and school leaders, the use of professional learning communities, the creation of a learning organization and an infrastructure that helps to mobilize evidence to enable practitioners to make sense of it and to translate this into effective teaching and learning strategies.

A simple Google Scholar key word search on some of these areas provides a picture of the shape of the field: (Table 1)

Table 1 Google scholar searches related to schools as research-informed learning organizations.

Search term	Number of returns (October 7, 2021)
"Professional learning communities" and schools	77,000
"Teachers as researchers"	11,500
"Schools as learning organizations"	1310
"Data use in schools"	930
"Research learning communities" and schools	472
"Research-engaged schools"	244
"Evidence-informed practice in schools"	39
"Practice-based research in schools"	32
"Research-informed schools"	13
"Research-informed school leadership"	4

The table above shows the maturity of some areas of scholarship, such as professional learning communities (PLCs), schools as learning organizations (LOs) and teachers as researchers. There has been a relatively recent uptick in publications in the areas of research-engaged schools (RESs) (e.g., [Godfrey and Brown, \(2019\)](#); [Dimmock, 2019](#); [Godfrey and Brown \(2019\)](#); [Godfrey and Handscomb, 2019](#); [Godfrey, 2016](#)) and research learning communities (RLCs) (e.g., [Godfrey and Brown, 2019](#)), albeit both of these are still limited to relatively few scholars. It also important to note some conceptual overlap between research on data use in schools and with scholarship on evidence-informed practice (EIP) ([Brown et al., 2017](#)). While recognizing the blunt instrument of a Google Scholar search, nevertheless, there appears to be a paucity of published work that looks specifically at research and evidence-informed leadership and EIP at school organizational level. Some recent additions to this work are explored later.

More systematic work by [Farley-Ripple et al. \(2020\)](#) on Use of Research Evidence (URE), points to the fragmented nature of scholarship in this area. Surveying a wide community of scholars in the USA and UK, conducting both a social network and bibliometric analysis, they identified the different strands of recognized, published work and key scholars across sectors and disciplines involved in URE research. The most influential scholars named were from: sociology (27%), political science (20%), organizational studies (14%), psychology (12%), and economics (2%). Multiple key words were used to describe this field too: policy studies (21%), knowledge utilization (18%), evidence-based or evidence-informed decision making, policy, practice (17%), research impact (15%), implementation science (11%), and knowledge mobilization (9%). In their network analysis they found low density and high fragmentation of scholars in this area; respondents nominated 185 references across a range of disciplines, policy issues, and publication formats spanning more than five decades, with articles from 57 journals, overwhelmingly from health and education fields. However, even the most referenced journal, *Implementation Science*, had only with five publications, and the most nominated author was Carol Weiss, but most were nominated by only one person.

Some of the complexity of this area is brought together via the concept of *research-engaged schools*, which will be outlined later. Before this, the two key terms within the chapter title will be explained, including some key distinctions and debates about them, that is: *learning organizations* and *research-informed practice in schools*.

Learning organizations (LOs) essentially do two things: they promote the learning of their members through the culture and structural conditions of the organization, especially through its leadership, and secondly, they feed this learning back into the organization itself, making it better adapted, effective or efficient in the performance of its key functions. In other words, the "learning" flows both to the members/staff in an organization and back to the organization itself in a relationship of mutual advantage. Based on extensive survey data from Wales and the use of component and reliability analysis, eight dimensions are proposed for schools as LOs, these are:

- (a) a shared vision centred on the learning of all students, (b) partners contributing to school vision, (c) continuous learning opportunities, (d) team learning and collaboration, (e) a culture of enquiry, innovation and exploration, (f) systems for collecting and exchanging knowledge and learning, (g) learning with and from the external environment, and (h) modelling learning leadership.

[Kools et al \(2020, p. 24\).](#)

Numerous and contested assumptions follow from the concept of LOs. These include the nature of a school "organization", the notion of "learning" itself and criteria for determining "improvement". To begin with, viewing schools as organizations may promote a business orientation to schools and to see them as isolated units instead of as part of a wider embedded system underpinned by values. For this reason, some have proposed schools as "institutions" as preferable to the term organization (e.g., [Glatter, 2015](#)). A further distinction relates to the disciplinary underpinnings taken by scholars. For instance, some work employs cognitive processing theories to explain information flows in organizations analogous to the workings of the human brain ([Friedman et al., 2005](#)). While these may be applicable to individuals, the charge is that, by anthropomorphizing organizations this ignores many of the institutional, historical and practical enablers and barriers that allow or prevent learning taking place in an organization. By

contrast, social learning perspectives see organizations as sites of social and historically located practices (Lave and Wenger, 1991). The latter provides the foundation for the voluminous work on professional learning communities in schools. While enjoying strong favor among many researchers and practitioners, PLCs can be critiqued for the tendency to assume a consensus or collectivist view of professional work that may belie tensions with the notion of professional autonomy as well as between individuals' different educational values and aims that may make collaboration difficult.

One of the critiques of LO scholarship is that it is replete with assertions and terms that are insufficiently underpinned by empirical evidence (Schechter and Mowafaq, 2013). While organizational learning (OL) as a field of academic study does not promote any particular model or ideal, the broad LO literature often does exactly this (Friedman et al., 2005). However, such ideals are hard to empirically test due to the complexity in ascertaining when and how LOs have been demonstrably better at exercising their functions than comparable organizations. In schooling, the issue also touches on concerns about the propensity for research to measure what is easier to measure rather than what is important to measure, especially by narrowing down improvement criteria to student attainment in standardized testing (Biesta, 2017).

Proponents of LOs nevertheless provide extensive theoretical rationales about the usefulness of promoting schools as LOs to serve the needs of society, students, the economy and so on. One of the arguments in favor of the view of schools as learning organizations is that they fit a 21st Century model of what is required of schools, to equip their students for the complexities of the (post-) modern world. With the advent of ubiquitous knowledge via the internet, the job of teachers is less about imparting information and more so than ever, about making students into expert life-long learners. To do so, it is argued that teachers need to be knowledge workers, skilled in the analysis of information, and creation of new knowledge through enquiry (Price and Weatherby, 2018). Teaching, as in other professional domains (medicine, law and so on), it is argued, should therefore be underpinned by a range of knowledge: that obtained during by and in practice, observation, from student data **and from research**, in other words, it should be "evidence-informed".

Part of the picture that leads to evidence or research-informed practice in schools is the "infrastructure" that enables knowledge to flow to and from the separate domains of research and practice. The debates about "useful" research in academia for instance, have a long history in education, for example, in the UK, with Lawrence Stenhouse's work in the 1970s. These will not be covered once again here in full but will be touched upon below in the positioning and critiques of the *what works* model. More recently, as part of efforts to bring research knowledge closer to practice, some countries have adopted country-wide knowledge mobilization strategies. Knowledge mobilization (KM) works at interpersonal, institutional and system level and can be defined as:

The active and dynamic process whereby stakeholders (e.g., research, practitioners, policy makers and community members) share, create and use research evidence, to inform programming, policy, decision-making and practice'

Malik (2016, p. 11), in Pollock et al. (2019, p. 27).

In the US, the Campbell Collaboration is a social science research network that produces and disseminates systematic reviews and other evidence to inform public policy and practice. In the UK, the EPPI-Centre has a similar mission and does this through developing methods for systematic reviews and research syntheses, conducts reviews, supports others to undertake them, and provides guidance and training in this area. They also study the use of research evidence in personal, practice and political decision-making, supporting those who wish to find and use research to help solve problems, and providing guidance and training in this area. In the UK, the Education Endowment Foundation (EEF) was established in 2011 to improve the educational attainment of the poorest pupils in English schools. The EEF aims to support teachers and senior leaders by providing evidence-based resources to improve teaching practice and students' learning. As well as funding research (particularly randomized control trials) they also have a widely used teaching and learning toolkit that synthesizes research and produces guidance on the effect sizes of numerous educational interventions. Since 2016, the EEF has funded a network of "Research-schools" in England whose remit is to mobilize knowledge from research to other schools in their area, with the aim of stimulating evidence-based school improvement (Gu et al., 2020).

Debates about the relationship between research and practice are manifold and complex, and affect the way that practitioners, especially school leaders and teachers, researchers and policymakers interact with research. A way to think about this, is to contrast the *what works/evidence-based practice* model with an improvement science approach. The "what works" model proposes the use of "rigorous" research to demonstrate the efficacy and effectiveness of educational strategies. The gold standard of this approach is to use randomized control trials (RCTs), where large scale experiments randomly assign students, teachers or schools to an "treatment" or a control group and then compare outcomes after an appropriate time span. The second predominant form of evidence is through research-syntheses that provide summaries of a wide range of research on issues relevant to the education sector. The idea is to summarize, using the best available research, which strategies practitioners, policymakers and school leaders should use. In the EEF teaching and learning toolkit, this is exemplified with reference to the effect sizes of various interventions, the strength of the evidence and the cost effectiveness of the approach.

Proponents of the *what works* model can point to the advances that these approaches have made in translating evidence into more useful, practical and understandable forms of output that teachers and school leaders are able to access more readily (e.g., Collins and Coleman, 2021). However, a critique of this model is the exclusionary view of evidence that favors experimental

approaches and undervalues other kinds of research (Wisby and Whitty, 2019). RCTs can address simple cause-effect relationships in relation to an educational strategies, that is, whether it works better compared to usual practice, however, they fail to address how and why this method works better. This is why most RCTs in education also have a strong qualitative component to them. However, this only partially addresses their shortcomings. For instance, it has been shown that random allocation to groups is frequently “subverted”, dosage and compliance in treatment groups can vary significantly - raising doubt about how much of the “treatment” actually reached this group. Finally, due to the long time span of research the local and political milieux can affect ongoing participation and motivation in an experimental trial (Camburn et al., 2016).

Further research throws doubt on the pre-eminence notion for RCTs in Education. Lortie-Forgues and Inglis (2019) conducted an analysis of 141 trials from the EEF in England and the National Center for Educational Evaluation and Regional Assistance (NCEE). They made two important observations: first that around 40% of findings from these trials were “uninformative”, remarking that, “Such trials allow us to conclude neither that an intervention should be implemented at scale nor that this should be avoided to prevent the waste of public money” (Lortie-Forgues and Inglis, 2019, p. 164). Secondly, they found very low effect sizes in the trials they examined – much lower than would be expected from the wider educational literature. While the authors offer variations potential reasons for this (including the laudible fact that both the EEF and NCEE publish all trials, including those with negative outcomes), the solutions they offer are themselves problematic, requiring extensive replication of basic research before conducting experiments, larger trial sizes, or tailored outcome measures. The last approach, while giving the potential to detect larger effect sizes, sacrifices comparability across trials, while the other two solutions require significant time and significant additional financial commitment.

Academic research is itself, best considered one of many forms of evidence and knowledge that “informs” practice. Therefore, the term EIP is preferred by many to evidence-based practice (EBP), since the latter fits the *what works* model outlined above (Godfrey, 2017a) and fails to capture the way that humans interpret and make sense of the world around them, reducing the educational process to a mechanistic ontology where the effects of interventions “go on behind teachers’ backs” (Biesta and Burbules, 2003). Not only does this create a disempowering model of professionalism, it also overlooks the practical uses of *theory* in educational practice, including its conceptual and enlightenment role, focusing as it does on applying only research outcomes (Godfrey, 2017a). Thus, for a school-based version of a learning organization connected to research, I propose a model of professional educational practice that is “research-informed”, that is:

An actively enquiry mode of professionalism that involves critical reflection and engagement in (“doing”) and with (“using”) academic and practitioner forms of research, taking into account both the findings and theories generated from them.

Godfrey (2017a, p. 438).

Some scholars go further and suggest the need for a new paradigm of improvement science, in which practitioners and researchers work together as improvers, instead of one providing the knowledge and the other “doing” the improvement. This contrast with the *what works* adoption of a technical-rational professionalism in which expert knowledge resides in the academy and closely guides the way practitioners should work (Schön, 1983). Two of the key pillars of improvement science are: (i) to understand why programmes are often implemented with wide disparities in effect sizes in different contexts; and (ii) to work efficiently, avoiding imposing new programmes for schools (and workload) on top of existing strategies (Bryk, 2015). The imposition of top down prescriptions for teaching does not address issues of consistency because this elides the judgment needed by teachers and school leaders to adapt strategies based on the demographics of their schools and students and to align policies efficiently and effectively alongside extant approaches.

Bryk (2015) suggests that to make this improvement science paradigm work, and to close disparities between what society expects of its education system and what it achieves, there is an urgent need for an effective Research and Development (R&D) infrastructure. Such an infrastructure should focus on improving teaching and learning in schools and allow for better analysis of the problems they face, and the alternative solutions to them – avoiding what he calls “solutionitis” in which one solution is imposed on top of another, without ever properly testing and evaluating the system and how it works to achieve success through its institutional routines, rules and processes. The aim of this R&D infrastructure would not just be to know *what can work* but also to develop the *know how to make it work at scale, in different contexts, and for different sub groups*. Later in this chapter, some recent research comparing models of R&D infrastructure will be discussed, drawing out the central principles from them.

Having outlined some of the definitions, assumptions and debates that underpin this topic, the chapter now turns to a concept of the school where research, along with other types of knowledge creation and use, forms part of an ecosystem that has the potential to enhance the quality of education. It is important to state that, it is possible to view research-led institutions akin to businesses that are looking to gain “market advantage” over their rivals. Arguments can be made about the benefits or otherwise of encouraging rivalry and competition between schools to raise the overall level. However, many have pointed out that at the system-level, while it may be “theoretically” possible for competition between schools to raise standards, in reality these conditions are rarely in place and tend only to lead to greater inequalities and inconsistencies in standards (e.g., Ladd and Fiske, 2003). More scholars, in education at least, have pointed to the advantages of collaboration at school level to raise standards (e.g., Ainscow et al., 2006). Therefore, the research-engaged school is envisaged as part of a collaborative, inter-connected education ecosystem aimed at producing policies and practices that are informed (and improved) by the integration of research knowledge.

The research-engaged school

The notion of an ecosystem of research-engaged schools (RESs) has been comprehensively outlined in an edited book which looks at various levels of the system and with a range of international contributions (Godfrey and Brown, 2019). In this book, the levels of the ecosystem are mapped onto dimensions employed originally by Bronfenbrenner (1979) in his research into child development. Applied to RESs, these are: the macro-system (educational values, the purpose of schooling etc); the exo-system (the institutional configurations, collaborations and policy outcomes of these values); the meso-system (organizational level, the inter-actions between those in the micro-system); and the micro-system (the direct interactions and influences of teachers, school leaders and practitioners on students). The “ideal” RES ecosystem requires alignment of numerous elements such as: teacher training, teacher professional bodies; the accountability framework, school networks, research-practice collaborations with universities and other bodies, the intermediary brokering of research to school practitioners and within school ongoing research use, encouraged by school leaders. Seen as an ecosystem, the relationship between elements is dynamic and mutually constitutive rather than a linear chain of cause and effect’ with (evidence-based) policy being “implemented” by research school leaders, teachers and other professionals. Instead, the ecosystem has levels of affordances from its state of equilibrium and feedback loops present in different elements and sub levels of the system. For example, the accountability system may encourage innovation and research-use, or dampen it through a process of institutional isomorphism, game playing and conservatism (Ehren, 2019). At the macro-level, values may encourage cooperation or competition, or suggest a narrow or wider view of schools in relation to society, communities and so on. The teacher training system may produce new teachers accustomed to engaging critically in published research or it may turn out teachers concerned more by short term exam-based targets and teaching to the test. Seen in this way, RESs discourage thinking about leadership of individual schools as the only unit of interest in encouraging research-informed practice, the ultimate goal.

The research-engaged school operates within the ecosystem as a sub level: the meso-system. This organizational level is crucial, as it concerns the relationships between micro-level actors – especially teachers but also other professionals and stakeholders – who have the most direct influence on educational outcomes and processes. The term “research-engaged school” was originally coined by Handscomb and MacBeath (2003) and was described as a school with a research-rich pedagogy, a research orientation, that promotes research communities within and beyond the school and with research at the heart of its policies and practice. Drawing on a range of empirical evidence and scholarship, the author (Godfrey, 2016 p. 306) describes the nutrients of a research-engaged school culture as consisting of: leadership that encourages research capacity building and distributed knowledge creation; a teaching profession that is informed by a critical engagement with research; a school that is set up consciously to be a learning organization; and one that is connected to the wider system, outward looking and belonging to various networks (Fig. 1).

The focus on the meso-system brings to the forefront the importance of leadership in research-engaged schools and of effective learning communities in particular. Dimmock (2016) describes RESs as lynchpins in a system that address three concerns:

1. How to bridge the research-policy-practice gap by mobilizing knowledge more effectively through knowledge producers and consumers working collaboratively
2. Valuing and integrating both tacit knowledge and academic coded (explicit) knowledge
3. Raising the professionalism and reflectivity of teachers and leaders

Godfrey and Brown (2019, p. 9).

Fig. 1 Nutrients of the research - engaged school “culture”.

Dimmock sees one of the roles of leadership of schools as being to increase its organizational capital, that is, “to change and redesign the school by making better use of its intellectual and social capital to produce high-leverage strategies of teaching and learning” (Dimmock, 2019, p. 58). Research-engagement is seen as key to achieving this improvement in the innovative and learning capacities of schools. He sees three key leadership tasks in this vein:

- i. To encourage teachers to be reflective practitioners, valuing evidence and research-based approaches
- ii. To build a school culture with expectations that leadership and teaching can be improved through research-engagement
- iii. To establish processes and structures in the organization that embed such ways of working, including sustaining and scaling-up research into practice.

Godfrey and Brown (2019, p. 60).

One of the ways that this shifts traditional leadership practices is that school leaders need to be cognisant of effective methods of bringing research into practice. In Godfrey and Brown (2019), two such models are proposed, including research-informed peer review and research learning communities. More recently a model of collaborative peer enquiry has been proposed (Godfrey, 2020). These models require participants to learn procedures and principles that, especially in the early stages of use, involve modeling by external (usually university based) facilitators, intermediary brokering of relevant research, and effective partnerships with other schools. School leaders need to focus on process rather than outcome accountability for those involved (usually teachers). This is because by only by adhering to the central principles and practices of the approaches will practitioners achieve the deep level of sustained learning they are designed to engender. Judging participants by outcomes such as short-term improvement in student attainment endangers this process and leads to conservatism and a mentality of performativity. This kind of accountability is likely to be counterproductive because participants feel more inhibited, less innovative and disinclined to share their areas for development with peers, focusing rather on proving to their superiors that they have made gains. Nevertheless, for researchers, the challenge remains how to convince practitioners that research-practice models are worth the investment of time that they require. This, among other themes, is explored below in terms of the current evidence in the field.

Recent literature related to research-engaged schools

The chapter now turns to what insights have been gained on this topic from 17 articles published from 2017 to 2021 covering a range of research topics pertinent to the issue of schools as research-informed organizations. Two overall areas will be explored from these. The first are studies comparing current EIP by teachers and school leaders in various countries and how to promote EIP. The second area is the evidence-base supporting research-engagement at individual, school and system level. The research covers 11 jurisdictions: England, France, The Netherlands, Canada, USA, Finland, Turkey, Australia, Sweden, Germany, Ireland. The studies employ a wide variety of research methods: systematic reviews, surveys, interviews, focus groups, case studies, mixed methods, document analysis, participatory action research; data templates, engagement data and professional reflection. Below the analysis is divided into two overall areas: 1) research and EIPs in schools; 2) the current strength of the evidence base supporting various aspects of research-engagement.

Research on evidence and research-informed practice in schools

Research from the articles in focus covers seven areas: a comparison of EIP and policies across countries and the barriers and facilitators to EIP in these jurisdictions; approaches to improving teacher evaluative and research skills; how school leaders can encourage inquiry-based school practices; teachers as embedded researchers; how teacher education programmes can contribute to a school’s research culture; the use of research-champions; a research-brokering initiative and finally a study of research use by the Swedish school inspectorate. The intention is to examine research concerned with all levels from micro-macro level of RESs.

System and practitioner (macro and micro level) patterns of research and evidence-informed practices in schools

Before examining the ways in which school leaders can influence research-engagement at the school (meso) level, looking at EIP in different national school systems can identify ways that macro-level environments affect teacher (micro) level research-engagement. Some of these reflect ideas and values about the nature of teacher (and other educators’) professionalism and the extent to which research plays a part in this.

Malin et al. (2020), examined the use of EIP in four countries and the formal and informal institutional rules that constrain or enable these practices. In a comparative case studies’ approach, they employed a range of secondary data, looked at EIP in schools in Catalonia (Spain), England (UK), Massachusetts (MA, United States), and Rheinland-Pfalz (RP) (Germany). They classified each region employing a cohesion/regulation matrix developed by Hood (1998). This four-quadrant matrix looks at the overall macro/system level factors that define school systems, comparing countries that have high or low social cohesion (SCO) and high or low social regulation (SR). In the fatalist way, the context is defined by rule bound approaches but with little cooperation (high SR, low SC). In the hierarchist way, social cohesion and cooperation is high and ends are achieved through rule bound and bureaucratic approaches (high SC, high SR). The individualist way involves a fragmented system with informal, negotiated approaches to operating (low SR, low SC). Finally, the egalitarian way involves high participation in decisions and lots of peer to peer support (high SC, low SR).

Table 2 Four region's positions on the social cohesion-regulation matrix.

	<i>High social cohesion</i>	<i>Low social cohesion</i>
High regulation	<i>The hierarchist way</i> Catalonia	<i>The fatalist way</i> England, Massachusetts
Low regulation	<i>The egalitarian way</i> Germany (Rheinland-Pfalz)	<i>The individualist way</i>

In this classification, Catalonia was assessed as having a hierarchist approach; the English system as fatalist, as was Massachusetts (albeit with complexities and some evidence of collaboration); while in Germany the approach was considered to be egalitarian (See [Table 2](#) below).

The analysis showed how these overarching values affected the ways in which evidence was used to inform practice. In Catalonia there was a diffuse, fragmented picture of school system and research use. Spanish teachers tended to disconnect the conception of research from educational practice, in favor of experiential and peer knowledge. National education reforms were themselves not considered evidence informed, and culturally, institutions tended not to have a research culture. In England there was moderate evidence of some research use by teachers, and the EEF toolkit and research schools were given as examples of enablers. However, a lack of time for practitioners to engage in EIP and budget cuts were considered highly significant barriers. In Massachusetts, a strong top-down approach was used to push certain types of evidence into schools. Nevertheless, there were some isolated examples of strong EIP and untapped potential for cross-district collaboration. "Data" was more often used than research-evidence, although indirect access of research through brokering institutions was also seen. Lack of time was also considered a barrier to EIP in schools. In Rheinland-Pfalz (Germany), data from new evaluation and assessment practices was distrusted, and research was rarely used to inform teaching quality. There was partial uptake of the idea of the school as learning organization, but the professional autonomy of teachers made organizational level change and research-engagement a challenge, albeit not an insurmountable one, for school leaders.

Further evidence of how top-down values permeate EIP comes from research by [Gaussel et al. \(2021\)](#) in the context of the French school system. The authors describe a situation in France dominated by centralized top-down control and in which teachers see school leaders as sometimes threatening to their professional autonomy. Lack of time to collaborate with others was also seen as a barrier to French teachers. In a survey of 172 primary and secondary school teachers, the researchers wanted to find out to what extent EIP was associated with school improvement and to what extent leadership and issues of trust could encourage EIP. Among other variables, the survey measured perceptions of research use (PoRU), climates of trust (CoT), and innovation (CoI), and climates of research-use (CoRU). The researchers found that French respondents were less favourable toward the idea that theory from research could contribute to their practice but open to research findings contributing. Weak correlations were found between all 4 factors, the strongest were between PoRU and CoRU. School climate that encourages research use was seen as the most important determinant of teacher perceptions of research use and more important than a climate of trust. However, as leaders in France have little instructional influence, the authors recommended establishing norms of research-engagement centrally, in the teaching profession.

Three studies examined research-engagement in the Australian school system ([Mockler and Stacey, 2021](#); [Rickinson et al., 2021](#) and [Prendergast and Rickinson, 2019](#)). There has been an increasing call for the Australian school system to use evidence for improvement in recent years (e.g., [Australian Productivity Commission \(APC\) 2016](#)) and for Australian schools to become research-rich ([Shore et al., 2017](#)).

[Rickinson et al. \(2021\)](#) studied how Australian educators find and use research and evidence. In a survey of 492 practitioners from 414 school across four Australian states, they were interested in finding out how schools were using research evidence, what was involved in using research evidence well and how quality use of research evidence could be developed. They found that research is sourced and used less often than other types of evidence but that school leaders had positive attitudes toward research use, especially when this was contextually relevant. They also found that teachers tended to rely on social methods to engage with evidence; and were concerned with time and access issues. Collaboration with other schools was seen as a key factor in determining uptake of research engagement, along with the contextual specificity of the evidence.

[Prendergast and Rickinson \(2019\)](#) were interested in multiple aspects of research-engagement. In a survey and focus groups involving principals and deputies from Catholic schools in Melbourne, they wanted to know about school leaders' reasons for participating in research projects, how research was used by teachers, and engagement by teachers in research-enquiry. The three most frequent reasons for agreeing to a project were when:

- (i) It was identified as an area of need of development in the school improvement plan
- (ii) the topic was of interest to staff, students, and/or families and:
- (iii) school leaders believed research would produce tangible outcomes.

The principal reason for not agreeing to a project were when demands on the school were considered too great. School leaders surveyed were clear that the most beneficial research projects included a capacity building and professional learning dimension. Regarding research use, schools accessed research in indirect and informal ways including conferences, professional associations and professional publications. However, they conceded that there was infrequent daily use of research to inform practices.

Mockler and Stacey (2021) looked at how teachers understood and engaged with educational research and data with the aim of understanding teachers' professional learning and development needs in relation to research and data literacy. Drawing on data from across two phases of a research project known as Teachers, Educational Data and Evidence-based Practice (2018), they interviewed 21 teachers, recruited via social media, and surveyed 524 respondents in a questionnaire. Acknowledging the bias of this group of self-selected participants, their results found that teachers were generally more well disposed toward research than data, with 63% declaring themselves to be data enthusiasts and 76% research enthusiasts. Over a quarter of the participants identified as data sceptics, while only 12% identified as research sceptics. Ninety-four percent indicated that they regarded teachers' own systematic observation and reflection to be the best source of evidence. Student learning and assessment tasks, interviews/focus group interviews with students, classroom observation by a peer and senior colleague, student surveys and in-class tests were also highly regarded forms of evidence. Less trusted, however, were "walkthroughs" by senior school staff, Higher School Certificate or leaving credential results, other external assessment data and national student test data. Analysis of the values of this group of research enthusiasts showed that some forms of evidence, especially those which were external accountability-driven, could be seen as adversarial and therefore not contribute to improved practice. Teachers valued internally generated evidence that showed how their teaching had improved.

The macro-level considerations about how evidence from research can and should influence practice, comes into studies of other actors in the education system. Segerholm et al. (2021), researched how educational research is used by the Swedish School Inspectorate (SSI). Their research looked at evidence-based governing of the school system and the implications of involving educational research in this process. The research explored, through case studies, two activities performed by the SSI: (1) regular supervision and the establishment of a common knowledge base for that supervision, and (2) The planning, design and conduct of quality audits. With the intent of enhancing research-informed practice, the Swedish government employed staff with investigative backgrounds and listed scholars as research resources for the SSI. Through interviews with school leaders, inspectors and educational researchers they found some tensions in how decisions were arrived at and viewed, through interactions between the various agents (inspectors, teachers, school leaders and researchers). When it came to generating examples of "good practice" in the audits, the researchers felt that it was necessary to problematize this in terms of the context of the practice, while the inspectors did not. Paradoxically, the researchers expressed concerns about their involvement in the inspection process; first about losing their independence and criticality by working for a state agency, secondly, they wanted to emphasize the voice of teachers and protect them from unwarranted criticism.

The Swedish study, as well as the Australian research, shows misalignment in values between accountability dimensions of research-informed practices with those of practitioners. This suggests that need to consider intelligent forms of accountability that complement school improvement efforts. Other clear commonalities in the findings from the above studies include the need to make research relevant and specific to schools, to be presented in accessible and user-friendly formats, to find ways to increase teacher time and staff motivation for EIP and to improve their confidence and capability to translate research into classroom practice.

The exo-system: models for collaborative research-informed school improvement

In addition to the overarching values about professionalism, accountability and institutional regulation and cohesion, the infrastructure of research and development (R&D) also plays a part in influencing the effectiveness of research in improving practices in schools. Several collaborative approaches and models have emerged that attempt to engage multiple participants and stakeholders—and not just researchers, from different organizations, to address problems requiring systemic change. For school leaders, policy makers and researchers in this area, it has become important to make sense of these different forms of EIP "architecture".

Penuel et al. (2020), looked at the similarities and guiding principles of four R&D models in USA, namely: Strategic Education Research Partnerships (SERP), Design-Based Implementation Research (DBIR), Networked Improvement Communities (NICs) and Community-Based Design Research (CBDR). In a day and a half meeting, presentations, and pre-reading of select papers, researchers and experts in these approaches used a Venn diagram to identify principles in common or that were distinctive to each methodology. Eight core principles were identified:

- 1 Participants should collaborate in research
- 2 Roles and contributions of partners to the whole venture need to be clearly defined
- 3 Stakeholders unite around a shared problem
- 4 Research should be sensitive to context
- 5 Research is valuable in that it provides something of practical value to the stakeholders and users of it
- 6 The research should look at intended and actual outcomes (and gaps)
- 7 Should be logical, specific plans and iterations to test out, refine and evaluate the approaches
- 8 The research should be valued by people/bodies outside of the partnership too.

While more research is needed to evaluate the merits of these four models, this study is a useful step in teasing out principles that many have in common and that experts agree lead to successful school improvement. With several R&D approaches vying for attention, the validity of such claims and relative efficacy of the above models can be further tested in relation to these precepts.

School (meso-level) factors affecting research engagement

While the focus of the above research looks at how system level factors influence research and EIP, the influence of school level factors, especially leadership is clearly important. The following section thus focuses on leadership roles and processes that are involved in promoting school research-engagement.

While R&D models such as those described in the above section have the potential to lead to changes in practice informed by research evidence, involvement in such projects may also lead to changes in the way things are done at school, that is, culture. In the Netherlands, Geijssel et al. (2020) examined the extent to which participation in funded R&D projects encouraged the integration of inquiry-based practices. To this end, 28 school leaders of Dutch secondary schools were interviewed retrospectively about their involvement in a series of R&D projects designed to improve teachers research literacy, to use research for accountability and diagnose and analyze problems of practice. School leaders in several of the projects said inquiry-based practices served the development of their schools; and external researchers and school leaders were able to work with teachers to develop their research skills, helping to get answers to school-specific issues. Teachers communicated research in presentations and practice demonstrations to the professional community. Some school leaders planned to apply for further funding for practice-based research and to integrate research as yearlong activity in their school improvement plans. External researchers were able to add specific expertise on research areas such as effective student feedback and organizational capacity was improved through knowledge sharing. In a minority of projects, research did not develop a professional learning community and in one case the problem cited was that the results of the research came too late to feed into teachers' learning.

A leadership innovation to develop research-informed practice in schools, particularly in the English context, is to use teachers, middle or sometimes senior leaders to coordinate research-engagement within the organization and in collaboration with partners. These research champions (RCs) are sometimes funded by the school directly, by virtue of external research grants or in ongoing school university partnerships. In an example of the latter, Burn et al. (2020) gathered data from nine RCs from a collaboration called the Oxford Deanery, linked to Initial Teacher Education (ITE) and Continual Professional Development (CPD). They looked at the strategic intentions of school-based research champions and the activities they carried out and with whom they carried them out. The researchers carried out data collection over 18 months and analyzed it using a cultural historical analysis of motivations and contradictions between the introduction of a new system and the continuation of the old one. Research champions were found to have two broad intentions: creating a research culture and supporting CPD and promoting knowledge mobilization and collaboration. Relationships with senior management were considered crucial, as well as "upward management" of knowledge. Research champions worked to build their own expertise and targeted teachers and departments more so than broader audiences, with little two-way response from teachers to RCs. However, RCs encouraged teachers to use research informed discretion and they performed a gatekeeper role, selecting relevant research for practitioners but also informing the university of what was relevant. Overall, the relational aspects of knowledge-mobilization were apparent in the work of RCs, making them interesting intermediaries in the process and, given the expansion of RCs, an area for further research.

Another innovative approach to bridge the academic-practice gap is to use teachers as embedded practitioner-researchers. In Australia, Blannin et al. (2020) studied schools implementing innovative learning environments (ILEs). Their research formed part of a much larger government initiative to change layouts of schools to improve learning spaces, across Australia. In this study, researchers from universities worked to develop school-based research and solutions. In this three-year study at eight schools, researchers worked with the schools to develop a mixed methodology to find out the school's current knowledge and practice regarding ILE's, to work out how to assist teachers and students in using spatial competencies to improve their teaching and learning and to gather evidence from the project. The study found leadership of embedded research in schools was helped by the support of a senior leader or a research champion. Senior leaders particularly helped with modeling, culture, trust and support through mentoring and time. Although linking teachers' professional development to school improvement was overall seen as a positive, sometimes this faced challenges if teachers were less personally invested in the research.

The above studies show how research-engagement can be promoted and supported by leadership roles in the school, either senior leaders or dedicated research champions and that leadership of research-engagement is also a relational process. Growing research use and enquiry is about changing the school's culture, so that such practices are built into day-to-day dialogue, planning and professional learning. The research itself, as already mentioned above, must not only be context specific but also timely if it is to feed back into practice in and effect change.

The strength of the evidence

Below, some of the evidence base on school research-engagement is highlighted from recent publications. This looks firstly at empirical support for linking research-engagement to school improvement, and then two systematic reviews of the literature are examined, one on the role of teachers in evaluating their own teaching programmes and another looking at the strength of the evidence underpinning various strategies for research use.

Perhaps the most difficult question to answer with certainty is whether and to what extent research-engagement and school improvement are linked. Bernhard et al (2020) interviewed 22 Head teachers, in seven deprived Boroughs of London to examine whether any such link could be found. Using a conceptual framework informed by the dynamic approach to school improvement (DAIS) (Creemers and Kyriakides, 2006) and research-engaged schools (Godfrey and Brown, 2018), they found that the most improved schools exhibited many of these characteristics. Two-thirds of their sample were found to be research-engaged and most of the other schools put a strong emphasis on effective professional development, which was itself guided by academic

evidence. In these schools, teachers and school leaders directed their work toward improving students' learning, including using learning walks. Many were strongly inspired by research and aligned their practices according to what they had read from the academic literature.

In other recent research, [Schenke et al. \(2017\)](#) found, from case studies of 19 secondary schools in the Netherlands, several positive outcomes from involvement in practice-based research. They looked at new knowledge created by performing research, which fell into three domains: innovation, teachers' practice, and the quality of the school organization. In 13 of the 19 projects research results were used to inform school development; and in some cases, changes to teaching practice were observed, such as in the use of feedback. Their research suggested overall that research-engagement played a strong part in professional development and inspiring improvement in these schools. Both this and the above study by Bernhard and colleagues corroborate previous research showing a moderate link between research engagement and student outcomes ([Rose et al., 2017](#)).

One purpose of involving teachers in their own research is to evaluate the effectiveness of their teaching or programmes. Using [Patton's \(2008\)](#) definition of evaluation as the systematic investigation of the effectiveness, worth, or merit of a program, practice or policy, [McFadden and Williams \(2020, p. 1\)](#), systematically reviewed the current literature. One of their questions was how such evaluative capacity could be developed in teachers. They found very few quantitative studies, nine were qualitative, none were experimental, and one quasi-experimental; three used pre and post design; three used cross sectional quantitative designs and two used mixed methods. The most common form of capacity building was support for teachers to undertake small scale research, including forming inquiry communities with university mentors and mostly conducting action research. Eight studies showed pre- and in-service teacher coursework and one study looked at research mentorship. Only one took a whole school approach to research, and this was perhaps a special case, being a Professional Development School in the Netherlands. Teacher skills development included: sourcing and evaluating research findings (research literacy); attitudes, knowledge, skills, and confidence in research processes; professional competences or reflective practice skills; teacher identity and self-efficacy; and collaboration, professional conversations, and collegial relationships. In this systematic review, the authors show a logic model in which short term changes from these activities were the development of increased skills and positivity toward research use, then in the medium term there was an increased use of a systematic research base and an empowered teacher identity, and finally more effective teaching was evident through increase in evidence-based practices. Important enablers for in-service teachers included release time, opportunities for collaboration and minimizing workload issues. An environment of research engagement and support from universities also increases confidence. Overall, this review supports the idea that school research-engagement can be intentionally nurtured and grown, and that intermediate markers that can be monitored along the way by school leaders to check its progress; these conclusions confirm findings in previous work (e.g., [Godfrey, 2016](#) and [2019](#)).

Which approaches most effectively encourage (high-quality) research use in education has not up to now been thoroughly evaluated. [Gorard et al. \(2019\)](#) therefore conducted a systematic review to answer this question, examining 323 studies from multiple sectors, screening for quality on: design; scale; missing data; measurement quality; and threats. They found very few robust studies, and most came from outside the education sector, very few showed the counterfactual needed to show what would have happened if the approach had not been used. In their research they show nine variants of evidence use (a–i) on the two dimensions: the extent to which this was modified, that is, plain (e.g., open access to journals), modified (e.g., EEf toolkit) and engineered (lesson plans/scripts), and the extent to which it was actively transferred, that is, passive (reading research), engagement in transfer (e.g., research champions or brokers), active, in transfer (e.g., teacher research). Their findings are summarized below: ([Table 3](#))

The above table shows two things, first the paucity of evidence in many areas suggests much more research is needed on research use in education. Secondly, only approaches c, h and especially f look particularly promising in the educational realm. Generally speaking, and especially for complex changes, active approaches to evidence transfer appear the most effective, albeit sources of passive evidence may play a first useful stage in a later more active process involving engagement or active transfer. Research on using a research-brokering initiative in Ireland ([McGann et al., 2020](#)) is a case in point. The T-REX initiative (teachers research

Table 3 Summary of systematic review of evidence on research use.

	<i>Passive transfer</i>	<i>Engagement in transfer</i>	<i>(Inter) active transfer</i>
Plain evidence	a does not work	b no evidence of change or improvement to practice	c limited evidence that this helps target research at concerns and because staff learn more about research use
Modified evidence	d evidence of engagement from downloads but not of changing practice.	e no evidence using knowledge brokers helps research use. May only work where change is very simple and partly accepted already.	f the most promising evidence. An audit approach and feedback/coaching is effective way to get evidence into use.
Engineered evidence	g no good evidence in education but feasible could work. However, concerns teachers might feel they are losing personal autonomy, for example, if given scripts in the way that nurses are given clinical guidelines.	h some evidence behavioral nudges/reminders can be effective but mostly as quick fix solutions.	i no good evidence however possible to legislate for EIP to be used but must only be most rigorous studies.

exchange) has a membership made up of over 2500 educational professionals from early years to higher education, with the aim of promoting communities of practice, inter professional dialogue through discussion, interviews, clips, and research stories. An example of cell e above, this may lead to more active engagement or transfer of research over time, without showing such an effect in the early stages.

Some caution needs to be attached to Gorard et al.'s methodology however, in that they use a particularly narrow definition of "rigorous" research within a *what works* paradigm (see above debate about this issue). Furthermore, they are looking at demonstrable effects over often short time periods of time on student (or other equivalent end user) outcomes. Research on whole school approaches to research-engagement tends to indicate cultural and structural changes which may take many years (Godfrey, 2017b), so strategies may become more, or less effective or appropriate over time. For instance, if teachers become more research literate, then "plain" evidence may have a greater effect and legislating the use of highly engineered, evidence-based practices could be counter-productive as it would be seen as impinging on teachers' professional autonomy.

Conclusions

The research linking research-engagement to specific school improvement outcomes is a burgeoning one and warrants further attention albeit this will remain a difficult one to support conclusively. As this research tends to be correlational, conducting longitudinal research where schools intentionally develop research-engagement and tracking trajectory over time may help illustrate this further. This approach is more feasible than comparing matched schools given the complexities of controlling the myriad of variables involved. Studies on research use are still lacking in education and more should be conducted testing the efficacy of various approaches. This research should however, employ a wide range of outcome measures, including at teacher level, and not rely solely on standardized student attainment data. From the little research so far, active approaches to research use look the most promising. This will come as little surprise to many who have worked with schools to apply research in practice in collaboration with practitioners and to develop cultures of research-engagement. Nevertheless, the principles of encouraging active research use still warrant further attention and testing of for the validity of their claims. The above work by Farley-Ripple et al. (2020) suggests there would be much to gain by bringing together different communities to understand each other's research traditions, terminology and contributions to an interdisciplinary conversation about research use. As the authors state, this will require coordination, investment, and opportunities to share learning.

Throughout most of the studies above, there is a recurring and common theme too: leadership of research-engagement is important, it takes time and is about changing the school culture. There are also structural factors built into school life and the teaching profession that are both easy to understand and difficult to resolve – teachers need time to be research-engaged and these practices need to be valued, and supported across the system.

Introduction

Turnaround leadership is an important research field, but not many scholars have examined the areas of continuity and change in this field since Liu (2020). Adopting Murphy's (2008) turnaround leadership review framework, this review fills this gap by exploring turnaround as a concept, a condition, a process, and a consequence in relevant research published between 2017 and 2021. This review also explores other aspects of turnaround leadership: leadership as a key to reintegration, why leadership change is necessary in low-performing schools, restraints on turnaround leaders, collaborative school culture and structure, antecedents of turnaround leadership, and the characteristics of effective turnaround leadership. In addition to documenting the ongoing efforts that have been made in these lines of research, this review also finds that there has been no significant progress in regard to school leaders as the cause of problems or the replacement of managers as signaling. New themes that have emerged in recent research include the role of principals in school turnaround, effective turnaround leadership practices, types of leadership, and the effects of district leadership in transforming turnaround schools.

Conceptual framework

Hallinger (2013) believed in the importance of limiting a review to a specific period for historical and pragmatic reasons. Liu (2020) concluded that more publications in turnaround leadership had emerged and prospered after Murphy's (2008) comprehensive review on the topic of turnaround leadership. Continuing Liu's (2020) efforts, this review focused on the relevant literature from 2017 to 2021.

Data sources

This review examined English-language book sections, peer-reviewed journal articles, and master's and doctoral students' theses on turnaround leadership in the education sector published between 2017 and 2021. In total, 44 publications were reviewed, including 28 peer-reviewed journal articles, sections or chapters from seven books, and eight doctoral theses. Multiple digital research databases such as ProQuest, ERIC, and EBSCOhost were searched for the aforementioned data sources. In addition, the researchers used Google Scholar to assist in the literature search. Guided by the literature collection strategy of [Murphy \(2008\)](#) and [Liu \(2020\)](#), key words used to identify the relevant publications included "turnaround leadership," "turnaround leaders," "principalship in school turnaround," "turnaround school leaders," "turnaround school principals," and "leaders/leadership in low-performing school."

The 28 journal articles come from the following international journals: *Journal of Educational Administration*, *Asia Pacific Journal of Education*, *Educational Administration Quarterly*, *Journal of School Leadership*, *Journal of Cases in Educational Leadership*, *AERA Open*, *Education Policy Analysis Archives*, *International Journal of Educational Management*, *Leadership and Policy in Schools*, *School Effectiveness and School Improvement*, *Journal of Education for Students Placed at Risk (JESPAR)*, *Journal of World Englishes and Educational Practices*, *Africa Education Review*, *NASSP Bulletin*, *Journal of Educational Administration*, *Journal of Educational Administration*, *International Perspectives on School Settings*, *Education Policy and Digital Strategies*, *School Leadership and Management*, *Educational Management Administration & Leadership*, *On the Horizon*, *International Perspectives on Leading Low-Performing Schools*, *School Leadership & Management*, and *Leadership & Policy in Schools*.

During the period between 2017 and 2021, multiple scholars published books on the topic of turnaround leadership in the educational context. [Hochbein and Mahone \(2017\)](#) published their first book in a series on school turnaround to help researchers and practitioners in the field to see through a few common and long-existing misconceptions (referred to by the authors as "myths") to better understand how certain schools decline or even fail in terms of performance, and, more importantly, how to more effectively reform low-performing schools. In the same year, [Hitt and Meyers \(2017\)](#) published their book and introduced some promising leadership practices that can produce school improvements. Another book, titled *International Perspectives on Leading Low-Performing Schools* and edited by [Meyers and Darwin \(2018\)](#), was one of the most significant publications during this period. Scholars from all over the world contributed chapters that shed light on the turnaround leadership in their respective countries or regions, such as Japan, China, Costa Rica, Chile, Germany, Malaysia, Indonesia, etc. Such literature helps researchers and practitioners learn from both successful and ineffective leadership cases from all over the world. 2019 saw the publication of two important books by [Murphy and Bleiberg \(2019\)](#) and [Petrich \(2019\)](#); the former reflected on a number of ineffective school turnaround policies and practices and identified some common barriers that may hinder or jeopardize school turnaround attempts, while the latter focused on the leadership practices of multiple elementary school principals who had succeeded in turning their schools around. Most recently, [Klein et al. \(2021\)](#) discussed, in a book chapter, effective leadership in schools that serve disadvantaged communities in countries such as the United States and Germany.

Method

The method used in this study was based on [Hallinger's \(2013\)](#) suggested considerations for a review:

1. What are the guiding questions?
2. What are the main conceptual perspectives that direct the selection, evaluation, and interpretation of studies?
3. What sources and types of data are adopted in the review?
4. How are data evaluated, analyzed, and synthesized in the review?
5. What are the major results, limitations, and implications of the review?

This study used [Murphy's \(2008\)](#) method to understand and synthesize the literature. The analysis was conducted using the following procedures. The initial analytical framework was derived from the main themes in [Murphy \(2008\)](#). These themes were coded using capital letters from A to K. Sub-themes were coded with numbers. For instance, "Setting direction" was initially coded as "4M," where the letter "M" represented the theme of "District leadership practices" used in transforming turnaround schools. The number 4 represented a specific district leadership practice. Then, the initial codes were grouped with other similar codes to form larger themes. For instance, "Setting direction" (4M) was grouped with other codes such as "Communication" to form the higher-level theme "District leadership practices." This particular example fell within [Murphy's \(2008\)](#) themes, but new themes were also added to the initial analytical framework as they emerged.

Findings

Turnaround as a concept

School "turnaround" is not a new or revolutionary notion. The scientific investigation of this topic can be traced back to organizational change and school effectiveness research about four decades ago ([Gerade, 2019](#)). Similar to many other sociological constructs, there is no universally agreed-upon definition for school turnaround ([Harris et al., 2018](#); [Hochbein and Mahone, 2017](#)). However, it is generally agreed to be different from regular school improvement or reform, in that it aims to enable drastic

change in schools with continuous underperformance in terms of students achievement and school development (Hochbein and Mahone, 2017; Meyers and Hitt, 2017). Hitt and Meyers (2018, p. 7) quantified turnaround as “a rapid and dramatic improvement in a school within the bottom 5% of schools that demonstrates at least 20% point gains in 2 years in both math and English Language Arts.” Mania-Singer (2018) pointed out that, according to the available literature, school turnaround denotes quick and dramatic change, but that in reality an increasing body of research has found that it generally takes a couple of years before meaningful and significant change (p. 139) is noticeable.

Citing Hochbein (2012) and other sources such as Collins (2009), Senge (1990), Pearson et al. (2015), and Gatewood and Gynelle (2020) summarized school decline into three scenarios: (1) a single event that sparks a significant decrease in performance, (2) a series of interconnected events that send a school into a gradual but noticeable downward spiral, and (3) an undetected slow descending trajectory (p. 46). Gatewood and Gynelle (2020) studied the decline of a school in the United States where the majority of the students were African American. They learned that, internally, a drop in the number of student admissions will have an impact on funding, which affects multiple areas such as the number of educational programs the school can offer and the number of teachers and managers the school can afford to hire (Gatewood and Gynelle, 2020, p. 105). Externally, changes that have occurred in the community can influence the performance of a school as well. Such influencing factors can include both inward and outward mobility of community members for reasons such as property values and taxes, especially when such mobility changes the racial or ethnic diversity of the neighborhood (Gatewood and Gynelle, 2020).

More often than not, school turnaround is a political or institutional decision or campaign rather than a voluntary endeavor undertaken by schools and their stakeholders. Turnaround has become a prevailing theme in the education policy of the United States as a response to the political and moral call to rescue continuously underperforming schools (Meyers and Smylie, 2017). In particular, in the United States, transforming turnaround schools has become an important political agenda (Mania-Singer, 2018; Meyers, 2020; Pham et al., 2020; Schueler, 2019). Although not as systematically developed, improving low-performing schools, especially those serving disadvantaged communities, has become one of the major foci of educational policy making in Germany (Klein et al., 2021). Furthermore, Tao and Liu (2020) reported that school turnaround in China has relied on school leaders’ developing an adequate understand the relationship dynamics between their schools and relevant governmental departments or institutions.

The continuity in this line of research has been that turnaround has mainly been viewed as a management concept and as representing a decline in the organization. Previous reviews (Liu, 2020; Murphy, 2008) have identified a relatively new theme in the area of turnaround as a concept: educational reform and turnaround as democratic processes. In addition, this review found a new trend: turnaround as a political concept. For instance, scholars have begun to describe decline as both a single event and an interconnected series of events, such as change in the demographic composition of a larger community triggering change in the student population of a school (Gatewood and Gynelle, 2020). In this approach to turnaround, school leaders need to have a good understanding of the political and policy situation in their country.

Turnaround as a condition

A large volume of the school turnaround literature has mainly focused on current low performance in a school and its potentially better state in the future, rather than on its troubled past (Meyers and Smylie, 2017). In comparison, much less literature is available that has discussed the factors that contribute to school decline and low performance (Gatewood and Gynelle, 2020; Harbatkin, 2020). To fill this gap, this section reviews literature that shines some light on the conditions that cause schools to be in need of turnaround.

Internal conditions

Internally, one of the essential factors that may cause a school to have performance challenges is related to the central focus of all educational activities—the students. Such complications may be the result of behavioral problems or high student turnover caused by a change in the racial or ethnical diversity of the student population (Harbatkin, 2020), or difficult conditions, such as socio-economic struggles or other life challenges, that students face outside the school walls (Coby, 2018). In addition to students’ personal challenges, risks factors at the school level can also have negative impacts on the performance status of a school, such as challenges related to school culture and climate, funding and resources, and the human side of school—factors related to teachers and administrators.

An organization’s culture and climate can greatly influence its performance and the effectiveness of its leaders, and schools are no exceptions (Harris et al., 2018). School culture and climate may contribute negatively to the development of a school and become the key factors resulting in its turnaround status (Whyte, 2018). Harbatkin (2020) discovered low or decreased trust among teachers and between teachers and students, the negative status of teacher leadership or school leadership, a low level of community support and involvement in school administration, and a high or increased level of violent behaviors among students may signal a drop in a school’s performance (pp. 86–87).

In addition to the intangible yet significantly influential factors that characterize school climate and culture, many low-performing schools are also economically disadvantaged with poor facilities and technological supports (Harris et al., 2018). However, Meyers and Smylie (2017) pointed out that superficial changes and improvement in the physical facilities of a school do not necessarily lead to fundamental and sustainable changes, and that schools need meaningful changes in their organizational behaviors if increased funding is to be effective.

Besides the environmental factors discussed above, the human side of the school organization plays a role too, i.e., teachers and school administrators. Such variables can include student-teacher ratio, the proportion of new teachers in a school, turnover of teachers as well as administrators, wages and other forms of compensation for teachers and principals, and so forth (Harbatkin, 2020). Furthermore, low teacher qualifications or the incompetency of school management or leadership can jeopardize students' learning outcomes either directly or indirectly through decreasing teachers' work motivation or commitment (Coby, 2018; Meyers and Hitt, 2017).

External conditions

Aside from the conditions and restraints within schools, there are also forces from the outside that, more often than not, are beyond the control of the school itself. Such external conditions can be poverty in a school's community, change in student composition especially in racially or ethnically diverse societies, and the imbalanced distribution of education resources (Harris et al., 2018). In their review of the relevant literature, Arar and Örüçü (2021) identified several other external unfavorable factors ranging from terrorism and high crime rates in the community, to students' diverse religious and cultural backgrounds, and rapid societal change.

The continuity in this line of research has focused on funding and resources (Harris et al., 2018; Meyers and Smylie, 2017). Research has confirmed that funding and resources are important for the successful transformation of turnaround schools, but that change in organizational and people-related factors may also significantly contribute to such transformation.

To sum up, as reviewed above, new developments in the internal factors related to transforming turnaround schools have centered on the human side of schools (Meyers and Sadler, 2018; Meyers and Hitt, 2017) and school culture and school climate (Harris et al., 2018). However, in the line of research, detailed strategies for developing school culture and school climate need to be further explored. Importantly, human-related factors like teacher motivation and well-being also require further exploration. Furthermore, extensive research on the roles of the external community in transforming turnaround schools is needed using diverse research methods (qualitative, quantitative, and mixed).

Turnaround as a process

There is a rich volume of literature describing the process of school turnaround. As mentioned frequently in the turnaround leadership literature, Leithwood et al. (2010) proposed breaking it down into three stages: stopping the decline and creating conditions for early improvements, ensuring survival and realizing early performance improvements, and reaching positive performance (Gerade, 2019; Liu, 2020).

Inspired and informed by such a framework, Yoon and Barton (2019) examined the notion of time in the process of school turnaround and proposed an innovative approach to school turnaround that the authors referred to metaphorically as *shifting gears*. In the first gear, turnaround leaders start by "repairing and rebuilding school climate and culture"; in the second gear, they "push for instructional initiatives and structures" to facilitate student learning; finally, they should try to imbed the instructional and cultural transformation into the school's DNA, so it can be sustained in the long run (Yoon and Barton, 2019, pp. 695–696). Similar to Yoon and Barton's (2019) final two steps, Hitt and Meyers (2018) emphasized two stages in the process of school turnaround: turnaround and sustainability. The "turnaround" phase demands school leaders' dramatic intervention, and the "sustainability" phase requires the continued use of both turnaround leadership practices and a gradual blending in of other effective leadership practices.

Similarly but more specifically, Harris et al. (2018) also introduced their summary of the turnaround process in Malaysia and Indonesia. At the beginning, principals attach importance to multiple aspects of reform such as institutional reorganization, the renewal of teaching staff, changing the school culture, and creating clear disciplines. During the more advanced phases of school turnaround, principals then concentrate on supporting teachers, increasing collaboration, and offering feedback about the improvement of instructional strategies. Furthermore, principals will also focus on monitoring students' engagement and learning outcomes.

The continuity in this line of research has been a focus on the conceptualization of the turnaround process in low-performing schools (Gerade, 2019; Hitt and Meyers, 2018; Liu, 2020; Yoon and Barton, 2019). The progress that has been made in this research has focused on the details of the change process. For instance, Harris et al. (2018) specified the precise strategies school leaders can use to transform turnaround schools. Additionally, it is notable that Hitt and Meyers (2018) described the sustainability stage, drawing the attention of turnaround leaders to combining varied leadership styles to improve their education practices. In future research, exploring the relationship between leadership styles and student achievement might deepen this line of research. In addition, further international studies on how to transform low-performing schools would solidify the knowledge base about effective change across cultures.

Leadership as a key to reintegration

Leadership plays an essential role in school turnaround and improvement (Liu, 2020). There has been a rich body of international literature with empirical evidence that has attested to the importance of leadership for improving students' achievement outcomes and the overall performance of a school in multiple ways (Leithwood et al., 2008; Lochmiller Chad and Chesnut Colleen, 2017).

Although there has been a large amount of interest in more democratic leadership styles such as distributed leadership, teacher leadership, and so forth, principals are still the central piece of educational leadership (Bush, 2020). Principals with proven talent and successful experience in school management and leadership play an undeniable role in turning around the performance of a school (Harbatkin, 2020; Meyers and Hitt, 2017).

Without a talented and experienced turnaround leader, struggling schools are not very likely to be turned around; therefore, a turnaround principal, together with the leadership styles and strategies that he or she chooses to adopt, serves as a catalyst that helps to stop a school's downward trajectory and to lift it up in a more positive direction (Wana, 2019).

Changing leadership as a key to turnaround

Strategic replacement of school leaders and sometimes part of the teaching faculty is a common measure in many school turnaround cases (Meyers and Smylie, 2017; Wana, 2019). This practice is believed to bring about the "necessary drastic disruptions" that are considered the "*sine qua non*" [italics in original] of school turnaround (Meyers and Smylie, 2017, p. 506). For example, Pham et al. (2020) evaluated the sustainability and maturation of school turnaround in Tennessee where replacement of the principals was a major component of the turnaround strategy. While agreeing with the necessity of such means, Meyers and Smylie (2017) also criticized that a change in leadership should not mistakenly be equated with the actual turning around of the suffering school. The continuity in this line of research has centered on the significance of replacing school principals in turnaround schools, but further research is required to explore the antecedents of successful turnaround leadership and how leaders can effectively empower teachers in the transformation process. Also, further exploration of the effects of replacing school principals would contribute to this field.

Rationale for leadership changes

As mentioned above, it is a common practice to replace the principal of a continuously struggling school, due to the frequent assumption that the original leaders in a struggling school may have become "too entrenched in the existing culture" of the school to bring about effective changes (Mania-Singer, 2018, p. 140). Instead, effective turnaround leaders "possess the knowledge and skills to stimulate quick and profound change that disrupts the original practices of the teachers and improves student learning outcomes" (Woulfin and Weiner, 2019). However, just like new CEOs do not always improve the performance of struggling companies according to management literature, a new principal hired from outside may not necessarily lift a poorly performing school out of its current problematic condition (Meyers and Smylie, 2017).

While short-term increases have been documented by researchers, Meyers and Smylie (2017) asserted that evidence of long-standing sustainable success is rare, unless the new principals deeply engage themselves in "the fundamental changes in school organization, operations and practices" that are essential to ensure that the new improvements last instead of withering away following the initial short-lived excitement of having a new leader (p. 510). However, Same (2017) also warned that we should not solely rely on certain leaders dropped in from the outside to magically save a school, but that all stakeholders of the school should collaborate with one another to ensure the success of the turnaround. The continuity in this line of research lies in the significance of the replacement of school principals in turnaround schools. The progress in this line of research has been recognition of the roles of different stakeholders in school organizations. This goes beyond the assumption that turnaround leadership only comes from the school principal.

Restraints on turnaround leaders

In both Western and Asian contexts, as mentioned above, prior successful leadership experiences cannot be mechanically transferred from one school to another with guaranteed results (Harbatkin, 2020; Paletta et al., 2017). In spite of the ambitious expectations and timelines in many school turnaround situations, turnaround leaders need to be aware of the restraints they face when diving in to turn around a low-performing school.

Political environment

The political environment from the national level to the local district level can have rather strong impacts on the turnaround of a low-performing school, in that it can influence both policy development on a macro level and the actual school district- or even school-level implementation of the turnaround measures as well as the principal's behaviors (Schueler, 2019). For example, China has adopted a highly centralized and top-down education governance model under which the government is in a hierarchically higher position and may enact certain restrictions over turnaround principals' power (Tao and Liu, 2020).

Resistance from the school and the community

It takes time for teachers and students in a school whose principal is reassigned, as well as the parents in the community, to understand and accept a new turnaround principal and/or his or her new visions and measures for the school (Hitt and Meyers, 2017; Same, 2017; Whyte, 2018). In a case study on turnaround leadership effectiveness conducted by (Same, 2017), the majority of the

participating turnaround leaders recalled resistance or resentment from both teachers and parents. Therefore, a turnaround leader cannot mechanically change everything, but “provide a synthesis of the past and the present to render sustainable change” (Whyte, 2018, p. 19).

Inability to perform

A turnaround principal’s effectiveness is to a large extent determined by his or her competence. This competence includes the principal’s own disposition as well as prior experience. A person’s experience can be the key to his or her success or the very reason that leads to setbacks; therefore, Hitt et al. (2018) regarded a turnaround principal’s prior experience as an essential contributing factor to the effectiveness of a turnaround principal. Such experience can come from previous firsthand work experience on the ground or from the preparation program he or she attended (Browne-Ferrigno and Muth, 2009; Hitt et al., 2018; Leithwood et al., 1996). However, based on empirical evidence, Adejumo (2017) asserted that principal replacement is not always necessary; if the principals of underperforming schools have open minds, so they will not be imprisoned by their previous knowledge and successful experience, they can evolve as capable turnaround school leaders, adapt in accordance to the current reality, and lift their schools out of their underperforming status.

Antecedents and factors affecting turnaround

Many factors can either provide aid for or hinder the result of school turnaround. For instance, as mentioned above, the original culture and structure of a school as well as teachers’ complacency about the status quo can create hurdles for turnaround attempts. Moreover, successfully turning around a struggling school takes time; while it is common for both the district and the turnaround leaders to see noticeable effects of the turnaround attempt, it is important for the stakeholders to allow enough time and patience, as well as necessary support during the process (Mania-Singer, 2018; Murphy and Bleiberg, 2019). It is also possible that some turnaround measures may also come across active resistance from teachers as well as the community, especially when the measures are perceived as loss (Murphy and Bleiberg, 2019; Pham et al., 2020). Therefore, it is essential for turnaround leaders to maintain active communication with these stakeholders and provide evidence of progress or success along the way. Other factors such as teachers’ experience and professional capacity, as well as teacher turnover, may also have significant impacts on the effectiveness of school turnaround (Pham et al., 2020). Moreover, as reviewed previously, many turnaround projects are part of the political campaigns or strategies of the local or even the state government (Mania-Singer, 2018; Meyers, 2020; Pham et al., 2020; Schueler, 2019). Therefore, another vital element in the success or failure of turnaround is the level of support a turnaround school receives from its superior governing body such as the district or relevant government division(s) (Meyers and Sadler, 2018).

Creating a collaborative school culture and structure

Just as Manla (2021) articulated, a school would not be likely to achieve any instructional or curriculum successes without an enabling culture and a climate that celebrates respect, clear expectations, recognition, personal responsibility, and so forth (p. 21). Turnaround leaders with a successful track record can be helpful for repairing and rebuilding school climate and culture, in that they are better at accommodating change—a crucial leadership quality turnaround schools badly need (Yoon and Barton, 2019).

Realizing and taking into consideration the importance of school culture and climate, a Southern US school district (Turner School District) explicitly included changing the school culture as an essential part of their strategy for the turnaround of the schools in the district (Meyers, 2020). Harbatkin (2020) also came to the conclusion from the literature that a change in school culture and climate is necessary for successful school turnaround.

If turnaround principals are to consistently apply the democratic and collaborative leadership styles that have been considered more effective in the school turnaround leadership literature, it is necessary for them to develop and maintain a school environment that allows for collaboration. In her doctoral research project on leadership reform in low-performing schools in the United States, Harbatkin (2020) identified that the amount of teachers’ time used for collaboration was positively related to school performance. In other words, when teachers spend less time on collaboration, there may be a decline in the school’s performance.

When turnaround leaders use supportive leadership strategies such as shared or distributed leadership, it is necessary to create an inclusive environment in the school where all teachers and staff, along with school administrators, can collaborate on a collective vision. In doing so, the school can mobilize all its manpower and resources to achieve better curriculum and instructional performance and change the downward trajectory of the school development in a positive direction (Huguet, 2017).

Principals’ role in school turnaround

However, not all well-performing principals can turn around a struggling school. Drawing on a substantial amount of literature, Meyers and Hitt (2017) pointed out a common belief that turnaround principals are fundamentally different than regular effective principals. For instance, they have higher levels of emotional intelligence and are usually better at making use of both support and accountability as well as catalyzing change in the chronically struggling school, while effective principals in already well-performing schools mainly need to maintain their good condition and practices (Meyers and Hitt, 2017).

Yoon and Barton (2019) also pointed out that turnaround leaders with a successful track record can be helpful in turning around a struggling school because they are more accommodating of change—a crucial leadership quality turnaround schools badly need. Reitzug and Hewitt (2017) asserted that turnaround principals need to be able to provide or instill a sense of vision or direction in the faculty, establish and strengthen connections with the staff, and at the same time help develop the capacity and efficacy of the teachers. These authors also argued that successful turnaround principals must be able to create “ongoing dynamic tensions” [italics in original] between elements such as direction, connection, and development in their schools and at the same maintain balance between them so as to disrupt complacency and the status quo and keep their faculty members “at the edge of their competence and capabilities” (Reitzug and Hewitt, 2017, p. 517).

Leadership practices in school turnaround

As mentioned above, each turnaround school has its unique conditions and challenges; therefore, the strategies and measures developed to turn them around should be tailor-made with consideration for the particular situation of each school rather than mechanically relying on the prior experiences of successful cases elsewhere (Harris et al., 2018). Wana (2019) argued that effective turnaround leaders ought to *maintain that focus on student learning, provide clear and consistent expectations, develop a clear sense of accountability, and adjust their instructional and leadership strategies based upon actual data from the turnaround process*. In addition, other effective leadership practices can include building and developing teachers’ professional capacity, create a collaborative and supportive school culture and climate, and connecting with external partners (Same, 2017).

Getting to know the terrain

Upon entering a failing school, it is unwise for turnaround principals to rush into looking for solutions without a thorough understanding of the root cause of the school’s struggles (Mania-Singer, 2018). Instead, it is essential for the turnaround principals to try, upon arrival at a low-performing school, to familiarize themselves with its history, its existing organizational culture and climate, and the strengths and weaknesses of the teachers and the students, so that they can develop a meaningful turnaround strategy that truly fits the school’s needs.

Setting up a new vision and planning

High-quality school improvement planning aligned with a resonating vision is an essential step toward improving the climate and student learning of underperforming schools (Meyers and Hitt, 2018). Without it, teachers and other supporting staff will not be able to find a clear purpose but will instead “muddle through activities” without knowing why (Huguet, 2017).

Redding and Searby (2020) extracted a fourfold school improvement plan from a rich volume of relevant literature: “(1) establish a shared vision, (2) set strategic goals that help achieve this vision, (3) identify areas of staff development, and (4) create measurable outcomes that can be routinely monitored by school, district and state personnel” (p. 69). However, to do so, turnaround leaders and policy makers ought to learn about and take into consideration the actual organizational context of the schools while planning (Meyers and Hitt, 2018).

It is a common assumption as well as practice for turnaround leaders to make short-cycled plans for the schools they are entrusted to save, but Meyers and Hitt (2018) discovered that, in reality, most of such attempts were unsuccessful, possible reasons for which include the following factors:

1. The plans and the goals or objectives are not clearly communicated within the school;
2. The components of these short-cycled plans are not aligned with one another or the priorities, goals, and vision of the turnaround mission;
3. These plans are not meaningful for or connected to the new vision and objectives.

Building trust and demonstrating respect

One important factor in a school’s culture and climate is mutual trust between the school administrators and teachers, as well as among the teachers. Principals are more likely to trust teachers who help in meeting school goals, while teachers are more likely to trust principals who display personal consideration and benevolence (Bush, 2020).

On the other hand, if teachers feel that they can trust the principals to provide them with support and encouragement, they inclined to be more enthusiastic and committed to their job and the organization (Huguet, 2017). Such a trusting and supportive school culture and climate will also have profound positive impacts on the behavior as well as the academic performance of the students (Wana, 2019).

Improving communication

Effective communication can help turnaround leaders better understand the current conditions and problems of the school. After learning the terrain, turnaround principals need to create or find a new vision with clearly defined goals and objectives, so that they can initiate and implement activities that truly pull the school in the intended directions of development (Huber, 2018). Successful turnaround principals use communication of ideals and beliefs to promote their turnaround campaign and also to influence and facilitate change in the mindsets of the teachers as well as parents. These changed mindsets then cause change in the teachers’ and parents’ behaviors and ultimately enable the process of turning the school around (Adejumo, 2017).

Turnaround leadership competence

Compared with past research, a new advancement in turnaround leadership research has focused on the effects of turnaround leadership on student achievement. Hitt et al. (2019) explored the internal states of principals who orchestrate school turnaround with improved student achievement. This research identified seven important competencies of a successful principal, including: Initiates and Persists, Inspires and Motivates Others, Elicits Intended Responses, Builds Capacity with Accountability and Support, Commits to Student Learning, Crystalizes Problems and Creates Solutions, and Uses Inquiry to Systematically Frame Problems and Solutions. The research indicated that only Inspires and Motivates Others and Builds Capacity with Accountability and Support had higher-level scores, while Commits to Student Learning had a low-level score.

District leadership in turnaround contexts

Meyers and Sadler (2018) specified 12 district leadership practices. For instance, district leadership promotes bold changes to prioritize turnaround work while involving multiple members of the leadership team to initiate change. District leadership not only demonstrates high expectations to principals and school leadership teams, but also provides suitable resource utilization and responds to key needs in a timely way. In addition, district leaders need to give sufficient authority to turnaround principals and prioritize the hiring of school leaders in high priority schools. Meanwhile, district leaders are required to ensure good recruitment, placement, and retention while holding teachers accountable for teaching performance. In this process, rigorous assessment is clearly aligned with fundamental standards. The authors also explained that district leaders need to have a curriculum strategy to guide teachers' work. Subsequently, a data-driven culture and student management data system are required for instruction monitoring.

Importantly, Meyers (2020) also specifies the district leadership practices that are necessary for transforming turnaround schools. This research found that Commitment to Equity is the primary responsibility for district leaders who wish to initiate change and improvement in turnaround schools. District leadership also needs to create necessary structures while prioritizing talent and sets of skills to lead the work in schools. In addition, Meyers (2020) suggested that district leaders need to plan intentionally and with urgency, aiming to motivate and engage teachers into the change process. Importantly, district leaders need to provide the supports that schools need. Furthermore, district leadership needs to cope with three tensions strategically: the tension between focusing on the mission or personal connections, the tension between high expectations and high trust and respect, and the tension between disturbing satisfaction and continuity.

Types of leadership for successful school turnaround

Not all schools are created equal. The leadership strategies that were successful in turning around one failing school are not guaranteed to be as effective in a different context; therefore, turnaround leaders have to be familiar with multiple leadership styles so that they can adapt to the particular context of the school they are trying to save (Gerade, 2019; Paletta et al., 2017; Yoon and Barton, 2019).

Leadership scholars have been attempting for a long time to make more systemic sense of different types of leadership styles in order to better inform both scholars and practitioners in the field. In as early as the 1950s, Tannenbaum and Schmidt (1958) brought forward their classic Continuum of Leadership Behavior that puts different leadership patterns on a spectrum with *boss-centered leadership* using managers' positional authority on one end and *subordinate-centered leadership* allowing more freedom for subordinates on the other. A more modern but similar conceptualization can be seen in the comparison between authoritative and democratic leadership styles. Another popular school of leadership thoughts pioneered by Bass and Avolio (1990) among other scholars divides leadership into a duality of transformational and transactional leadership. Building on top of the previously available leadership knowledge, upon the beginning of the 21st century, leadership scholars developed a new perspective in the robust leadership literature—distributed leadership (Grint, 2011). More recently, Makgato and Mudzanani (2019) divide leadership into task-oriented and relationship-oriented styles. According to the scholars, task-oriented leaders emphasize more on the completion of the tasks but such an approach cannot effectively promote the team members' creativity and innovation. In contrast, the authors posit that relationship-oriented leaders support, motivate, and develop their subordinates, and that they foster positive relationships in the workplace and try to create open channels of communication.

By and large, supported by the recent literature, many turnaround leadership scholars believe that more subordinate-centered, democratic, and transformational leadership styles are more effective in elevating underperforming schools. For instance, Makgato and Mudzanani (2019), who has been mentioned above, conclude that relationship-oriented leadership approach can have a positive influence on students' learning performance. Such arguments resonate with the leadership practices reviewed above—effective turnaround leaders try to create a workplace culture filled with trust and respect and empowered with effective communication. In the same article, the scholars also assert that relationship-oriented leadership approach is not any particular single leadership style; instead, it integrates democratic leadership, transformational leadership, and shared instructional leadership.

With a similar tone, referring to recent literature, [Lochmiller Chad and Chesnut Colleen \(2017\)](#) also point out that effective leadership in schools does not rely on any single style but is rather an integration of transformational, managerial and instructional leadership behaviors (p. 86). Drawing upon data collected from 15 turnaround school leaders in LA County, [Same \(2017\)](#) also found that leadership practices under transformational and situational leadership styles are more effective than other approaches. Such research findings are also in agreement with what has been mentioned earlier that effective turnaround leaders should get to know the situation of the school they aspire to help instead of imposing measures from their past experiences. After all, each under-performing school has their own unique challenges.

Informed by multiple years of leadership literature, [Meyers and Hitt \(2017\)](#) noticed that distributed leadership has been given a significant amount of attention and emphasis. [Huguet \(2017\)](#) also echoed that collaborative leadership styles such as shared leadership, distributed leadership, and teacher leadership are most effective in positively influencing school performance. [Miles \(2018\)](#) identified that distributed leadership and teacher leadership had positive effects on the turnaround of a case school by revitalizing the school culture and improving the mutual relationship between teachers and students.

Similarly, drawing on the literature on leadership styles such as instructional leadership, transactional, and transformational leadership, as well as contingency leadership, [Petrich \(2019\)](#) studied how principals who successfully turned around failing elementary schools adjusted their leadership behaviors in a mid-Atlantic school district in the United States and identified five effective leadership practices: “inspire a shared vision, model the way, challenge the process, encourage the heart and enable others to act” (p. 77). In his doctoral research project, [Wana \(2019\)](#) assessed successful turnaround principals in Minnesota in the United States, and identified empirical evidence of similar leadership behaviors.

However, [Harris et al. \(2018\)](#) point out that turnaround leadership literature is largely Western-centric, and therefore has paid much more attention to more democratic leadership styles or approaches, such as distributed leadership, transformational leadership, teacher leadership, and so forth. One major reason for such a preference is that culturally western societies have much lower hierarchical power distance than other countries or regions especially in Asia. For instance, according to the big-data calculation by [Hofstede Insights \(2021\)](#), the Power Distance Index in many Asian countries is twice or three times as high as Western societies in North America and Europe. Through a case study in 10 successful turnaround schools in Malaysia and Indonesia, the authors also identified that many effective turnaround principals in Asia adopt top-down leadership approaches, considering themselves to be moral leaders and role models for teachers to follow rather than placing teachers at the center of the stage. [Harris et al. \(2018\)](#) contributed greatly to this line of research by exploring the emergent context of turnaround leadership. The development of the understanding of turnaround leadership in the literature has been illustrated through further exploration of themes related to such leadership. However, future exploration of the effects of turnaround leadership and the paths to improve student learning and achievement is necessary.

Conclusions

In total, 44 publications were reviewed, including 28 peer-reviewed journal articles, sections or chapters from seven books, and eight doctoral theses. These publications provides a relatively clear picture of the research progress and future research directions in turnaround leadership. Some important findings includes the leadership roles, quality of principals, replacement of principals, restraints on school principals, and districted leadership. This review emphasizes leadership’s role in integrating various turnaround processes, but the specific ways in which this integration takes place needs to be further explored. For example, [Bush \(2020\)](#) confirmed that it is efficient to retain the school principal’s role as the ultimate leader in school management, even when using a democratic leadership style. In addition, [Harbatkin \(2020\)](#) and [Meyers and Hitt \(2017\)](#), confirmed the importance of principals with good qualities and successful leadership and management experience in the process of transforming turnaround schools. Replacement of the school principal has been a widely used method to conduct school turnaround in the field. It is worth further exploring the effects of replacement of the school principal on turnaround school transformation. Principal replacement might benefit the receiving school. Also, the sustaining turnaround is problematic when the original school principal was commissioned to another turnaround school. It will be meaningful to further explore how turnaround schools can further develop their school principals to be effective turnaround principals.

In terms of restraints on school principals in turnaround contexts, this review identified that the political environment, resistance from the school and its community, and the principal’s own lack of ability can restrain a principal’s work. An understanding of the political environment is important for school principals to transform turnaround schools effectively ([Schueler, 2019](#)). District leadership in turnaround contexts was another research trend that has been picking up its momentum in this field. [Meyers and Sadler \(2018\)](#) specified 12 district leadership practices, among which providing support is crucial. This emerging field needs to be further explored to understand effective transformation in different contexts. Overall, the important aspects of turnaround leadership research have made new progress, but substantiated evidences are required for further understanding this field.

Introduction

Ensuring equitable opportunities and outcomes for all students is an enduring vision for educators and policymakers across the globe. Although equity has been an abiding concern in various educational reform efforts, accountability policies have intensified the use of data to illuminate and address differences in achievement across racial, linguistic, and income groups. Data on student achievement are now ubiquitous in schools and school systems. Large-scale assessment data are widely available in a large number of countries, and many schools and systems are supporting teachers to engage in formative assessment as well. There is a heightened expectation that data will inform decision-making in all aspects of schooling.

A growing body of research has been published examining the supports and constraints for data use, the role of teachers and leaders in the data use process, professional development for data use, and the successes and challenges of engaging in data-driven decision making (e.g., Coburn and Turner, 2011; Lai and Schildkamp, 2016; Mandinach and Honey, 2008; Marsh, 2012; Means et al., 2009; Schildkamp and Poortman, 2015). The research on data use tends to be dominated by conceptual frameworks rooted in organizational learning (Christman et al., 2009). In an organizational learning framework, the focus is on identifying problems, creating action plans to solve them, and developing a collaborative culture of inquiry (Christman et al., 2009). Data use is conceptualized as part of a cycle of instructional improvement (Goertz et al., 2010) in which individuals engage in a process of defining a problem or setting goals, gathering data, analyzing data, followed by action planning and evaluating outcomes (Coburn and Turner, 2011; Schildkamp and Poortman, 2015).

The cycle of instructional improvement has its roots in the plan-do-study-act cycle of Total Quality Management, an approach that was prominent in the corporate sector in the 1980s (Goertz et al., 2010). These frameworks are not only common in data use research, they are also widely prevalent in school, district, and state data use practices (Goertz et al., 2010). Meanwhile, researchers have explained that the process of data use is more complex, contextual, and less rational than this linear model might suggest (e.g., Coburn and Turner, 2011; Schildkamp and Poortman, 2015; Vanlommel et al., 2017).

Power issues and other social justice concerns are features of the data use process, although many studies of data use have not focused on these elements. Power comes into play as individuals in higher level positions use data use processes as a form of managerial control, influence which data are prioritized, or influence interpretations of data (Coburn and Turner, 2011). Some problematic data use practices further marginalize low performing students, such as publicly displaying test scores (Neuman, 2016) or engaging in “educational triage” by focusing remediation efforts on students on the cusp of proficiency (Booher-Jennings, 2005; Gillborn and Youdell, 1999). Equity concerns related more broadly to high stakes accountability systems, such as a narrowing of the curriculum in schools serving low-income students of color, have also been raised and associated with data use (Diamond and Cooper, 2007; Lipman, 2004).

Large-scale accountability policies, while drawing attention to systemic inequities, are often narrowly focused on highlighting student achievement gaps at the expense of understanding and mitigating the effects of unequal educational conditions and processes. Reform efforts have consequently focused on ways to close these gaps. We concur with Ladson-Billings (2006) who argues that the term “achievement gap” unfairly constructs low-income and minority students as defective and lacking and places the burden on students to catch up. Instead, using the term “education debt,” moves us to a discourse that holds educators and policymakers accountable for providing students access to the educational resources that will allow them to achieve at high levels. Ladson-Billings further advocates for deploying our best research knowledge, skills, and expertise to alleviate the poor educational conditions and learning experiences that students receive in many schools. Ladson-Billings’ arguments dovetail with those of Valli et al. (1997) who explain that, “Equity has replace the older concept of equality of opportunity ... equity places more emphasis on

[☆] This chapter is an edited version of the following article: Datnow, A., and Park, V. Opening or closing doors for students? Equity and data use in schools. *Journal of Educational Change*, 19 (2), 2018, 131–152. It has been reprinted with permission.

notions of fairness and justice, even if that requires an unequal distribution of goods and services” (p. 254) for equitable outcomes to be achieved (cited in Gillborn and Youdell, 1999, p. 3).

Data use could be an important lever for achieving equity and ameliorating the educational debt, but how and under what circumstances this may occur has not been well documented. It is important to reflect upon the question, *how do data use practices open or close doors for students?* The aforementioned studies provide insight into some of the equity issues that may arise with data use, but a more thorough investigation is in order. In this article, we draw on prior research and data from our qualitative own studies to discuss the tensions that educators face in using data and the consequences for equity. We argue that an equity agenda needs to be at the forefront of the field’s understanding and study of data use in schools.

Equity issues that arise with data use

Data-informed decision making can help schools monitor their progress toward equity goals (Skrla et al., 2004). But we cannot simply promote data use and expect good things to happen. Educators play a critical role in shaping how and why data are used, what counts as data, and what people are aiming for when they push the use of data in schools (Coburn and Turner, 2011). Data do not drive decisions by themselves (Dowd, 2005). Data-informed decision making is thus a more appropriate term for educational practice (Knapp et al., 2007). Although the term data-driven decision making is commonly used in the field, from here onward we will refer to the practice as data-informed decision making to signal this important shift in thinking about data use.

Our interest here is uncovering the ways in which data use may serve to open or close doors for students. There are a variety of ways in which data can be used in the service of expanding students’ opportunities to learn. Data can be also used, sometimes inadvertently, to limit students’ opportunities. We bring both extant literature and our own research findings to bear on a set of data use practices in which some of these core tensions are present. These include tensions between:

- Accountability-driven data use and data use for continuous improvement
 - Data use meetings focused on instructional improvement and administrative compliance
 - Focusing on standardized test data and using multiple types of data
 - Focusing on narrow bands of students and carefully examining data on all students
- Using data to confirm assumptions and using data to challenge beliefs
- Using data for tracking and flexible grouping to promote student growth

In exploring these tensions, we are not suggesting that these are dichotomous practices, with each existing on one end of a spectrum. In reality, there are a range of practices undertaken within each realm, some of them existing simultaneously within the same school. For example, it is quite common to find districts that focus primarily on large scale assessment data, whereas teachers are much more inclined to look at students’ achievement holistically (Coburn and Talbert, 2006). Within the same school, we can find educators who use data to confirm assumptions about students, as well as those who try to use data to challenge beliefs, and educators who do both, depending on the context. So too, even in schools that use data to track students, we find educators using data in the service of flexible grouping. Our aim is to explore some of the equity issues that arise along these dimensions, while elucidating the complexity and variation in data use processes.

Accountability-driven data use and data use for continuous improvement

Accountability demands have figured strongly into data use in many countries including the Australia, Belgium, the Netherlands, the United Kingdom, and the United States, among many others (Pierce and Chick, 2011; Mandinach and Honey, 2008; Schildkamp et al., 2014). What is clear in the literature is the delineation between high-stakes, accountability-driven data use, which emphasizes complying with external pressures and bureaucratic demands, and data use for continuous school improvement and organizational learning. Across the globe, educators often have to balance these two competing agendas simultaneously (Lai and Schildkamp, 2016). As educators balance various demands, key decisions are made with respect to data use and equity.

Firestone and Gonzalez (2007) explain that an accountability-driven data use culture focuses primarily on raising student test scores and tends to have a short-term time frame. Data are used mainly to identify problems and monitor compliance. When the stakes are high, “data can slant the system toward trickery and treachery” (Hargreaves and Shirley, 2012, p. 39). These misuses of data and the overemphasis on test score data have led policymakers in some places, such as Wales and Alberta, to abolish assessments at various grade levels (Hargreaves and Shirley, 2012). Other countries, such as Finland and Germany, test only a subsample of students rather than engaging in high-stakes testing of all students and, as Shirley (2017) explains, “This has sheltered German educators from the curriculum narrowing that occurred in US schools” as a result of No Child Left Behind (NCLB) (p. 61).

In contrast to accountability-driven data use, Firestone and Gonzalez (2007) note that data use for continuous improvement focuses on student and organizational learning and instructional improvement and is long-term in scope. In this model, data are used for diagnostic purposes and with integrity (Shirley, 2017). Data are used as part of a reflective process aimed at enlightenment and guiding and mobilizing action to improve the school over time (Firestone and Gonzalez, 2007). Also, while

continuous improvement can be a useful frame for data use, equity issues may still go unexamined, unless problems are framed as such, as we will explain. However, a continuous improvement focus is more likely to cohere with equity than an accountability focus.

It is also important to note that even when data use is framed in terms of continuous improvement, educators still may experience data use as a form of accountability. In Goertz et al.'s (2010) study, while the district's implementation of benchmark assessment was ostensibly aimed at continuous improvement in mathematics, teachers felt pressured by principals. "If you don't do well, you get talked to," explained a teacher (Goertz et al., 2010, p. 76). School context also matters. As Diamond and Cooper's (2007) study of Chicago showed, higher performing schools could meet the vision of using data for instructional improvement, whereas low-performing schools who were under sanction looked for quick-fixes to get out of probationary status. Many of these probationary schools served large numbers of low-income students of color and were characterized by a narrow focus on particular forms of data, as well as targeted students, grade levels, subject areas (Diamond and Cooper, 2007).

Data use meetings focused on instruction and administrative compliance. Leaders help set the tone for data use among teachers, focusing them away from or toward accountability, continuous improvement, and equity concerns. Correspondingly, the tension between accountability and continuous improvement is reflected in whether teacher collaboration meetings are seen as a place for genuine inquiry around student learning, or whether they are administratively regulated around compliance demands related to data use. These different foci have other important implications for equity, particularly when we consider the types of schools in which these different patterns of data use take shape. The focus on data use solely for accountability purposes (or not) shapes the decisions about what data are used, as well as how discussions among teachers unfold. Because professional learning communities are often the primary vehicle by which teachers learn to use data, the character of them matters a great deal (Daly, 2018; Jimerison and Wayman, 2015; Marsh and Farrell, 2014). As Huguet et al. (2017) argue, if teachers have unequal opportunities to learn, so will their students.

Horn et al. (2015) study found that teacher workgroups used different logics when interpreting the same district math assessment data. One teacher work group was focused on instructional management, spending their time categorizing students according to achievement levels. This teacher work group's instructional management logic aligned with the principal's focus on accountability. They adopted his frame of data use as a monitoring activity, rather than as a vehicle for examining students' mathematical understanding. In contrast, another teacher work group's discussions focused on instructional improvement, including deeply investigating the source of student mistakes. This pattern has been documented in other studies as well. Gannon-Slater et al. (2017) found that an accountability-focused data culture at the school they studied led teachers to focus on the technical dimensions of teaching and "what works," displacing equity aims. Huguet et al. (2017) explain, "In some cases, the work in a PLC [Professional Learning Community] can lead to evidence-based conversations that lead to a re-thinking of instruction, while in other cases, teachers can experience PLCs where time is invested in more procedural matters rather than reflection and learning tied to data" (p. 378).

In our own research, we have also observed different orientations in the teacher team meetings we have observed. In our earlier studies, numerous schools utilized data analysis protocols and tools in teacher team meetings. Many teachers described productive work related to these data discussion protocols (Datnow et al., 2012). However, in other cases, the administrative regulation that accompanied the protocols led some groups of teachers to focus on the tasks (e.g., completing a form describing the outcome of their discussions of data), rather than on meaningful discussions around data and instructional improvement. For example, in one data team meeting we observed, the overall point of the meeting appeared to be making sure that all parts of the protocol were addressed. With the focus on form completion, teachers spent less time engaging in a deep discussion of instruction.

We have also found that teacher team meetings can have competing purposes, defined by teachers in terms of instructional improvement but in terms of accountability by the principal. Park et al. (2013) reported on schools and districts in which leaders strategically framed the use of data in an effort to produce more equitable learning opportunities and outcomes for all their students. These leaders constructed sensemaking frames that centered on the need to confront disparities in opportunities-to-learn, school improvement as a shared collective responsibility, and making incremental structural and cultural changes to ensure sustainability of reform goals. The school principal and a coach in a school we studied redirected dialog toward students' strengths rather than weaknesses and oriented the conversation around improving practice (Park, 2018). In both of these cases, we see a deliberate commitment on the part of leaders to frame data use for instructional improvement as an *equity-driven activity*.

Focusing on standardized test data and using multiple types of data. Educators' and policymakers' decisions about what counts as data play an important role as well. Standardized tests themselves raise questions from an equity standpoint as they have long been criticized for their orientation toward forms of knowledge that privilege white, middle-class students (Garner et al., 2017; McNeil, 2002; Santelices and Wilson, 2010). As such, they put students from marginalized communities at an unfair disadvantage. High stakes testing also "creates intense, unfair pressure for teachers and administrators to raise scores in a system that does not support success for students of color, emergent bilinguals, and students from low-income families" (Garner et al., 2017, p. 422). These are concerns with standardized tests not with data use per se, but it is important to note that these issues arise when data use is narrowly defined to large-scale accountability measures.

With these important pitfalls of data use in mind, it is essential to address the relationship between federal and state accountability policies and data-informed decision making. First, the emphasis on using evidence (broadly speaking) to inform educational decision making is not new and can be found in many earlier reforms in and outside education. Thus, we should not confuse data use and accountability, nor should we assume that the two must be linked. The problem is that the type of data use that is connected to accountability policies is one that is narrowly construed, both in terms of what data is used and how it is used. Accountability

policies have prompted many districts and schools to be more focused on data use (Ingram et al., 2004; Marsh et al., 2006). These accountability pressures also motivated many districts to adopt benchmark assessments aligned to state tests in order to examine on an interim basis how students were achieving relative to state standards (Braaten et al., 2017; Jimerson and Childs, 2017; Snodgrass Rangel et al., 2017). In some cases, examining data on benchmark assessments has motivated teachers to look at a range of other information that can inform them about student learning and guide instructional changes (Datnow and Park, 2014). In other instances, data use is organized *only* around these benchmark assessments and has led to problematic consequences, such as a district's strong accountability orientation inadvertently compromising teachers' attempts at meaningful instructional improvement (Braaten et al., 2017).

Educators focused on continuous improvement actively seek out a wide range of data and do not limit themselves to data linked to accountability mechanisms. In our own research, we found that the sources of data that teachers actually relied upon went well beyond external assessment measures and included teacher created assessments, curriculum embedded assessments, writing portfolios, results from student work with online instructional tools, and of course their own observations of student learning. Drawing on this wide range of data allows for a much fuller portrait of student learning, allowing for a greater possibility that the strengths of students will be evident (Datnow and Park, 2019). Using multiple forms of data to inform instructional decision making can help provide a more holistic picture of student achievement and provide more ways to see evidence of student growth. This allows for a greater possibility that the strengths of students who have historically been disadvantaged by standardized measures will be evident. Drawing on a wider range of data may also lead to more informed, differentiated instruction (Park and Datnow, 2017).

Conversely, focusing on limited data, especially data from high-stakes assessments that are themselves biased against low-income students of color, can work against equity goals, contributing to narrow instructional goals and higher dropout rates (McNeil, 2005; Valenzuela, 2005). As Valenzuela (2005) argues, "When the test is the sole or primary arbiter in decisions with such long-lasting consequences for children, we insist that students have the right to be assessed in a complete and fair manner, using as many criteria as may reasonably indicate children's cognitive abilities and potential" (p. 2). At the same time, while using multiple forms of data is necessary, it is not sufficient, as we will explain.

Focusing on narrow bands of students and carefully examining data on all students. Under increased public scrutiny, NCLB and related policies in the US provided rewards and sanctions for schools based on the number of students who are performing at or above grade level. As one unintended consequence of NCLB, educators in Texas engaged in "educational rationing and triage" by examining state assessment data to determine which students are on the "bubble" or cusp of grade level proficiency and then investing resources to push these students over the threshold of the proficiency marker (Booher-Jennings, 2005). The same practice was used by low performing schools in Chicago (Diamond and Cooper, 2007). These practices were not limited to the US, however, as Hargreaves and Shirley (2012) documented a school in Ontario that focused test preparation on the 20% of students just below the passing mark. We found a similar pattern in our own research (Datnow and Park, 2014, 2019). Students who are very low performing were considered "lost causes," and those performing above grade level were not focused on either. This "educational triage" approach leaves many students behind (Booher-Jennings, 2005). By focusing on the use of data to avoid sanctions, educators, intentionally or unintentionally, subvert the intended goal of these policies.

This focus on students on the bubble shows up not just in individual teacher planning, but in teacher conversations as well. Halverson et al. (2007) found that faculty data discussions overwhelmingly centered on helping students below proficiency levels with few discussions focused on raising students from proficient to advanced levels. While such practices may result in greater numbers of students achieving "above the mark," they inadvertently compromise the overarching purpose of data driven practice, which is to expand opportunities for all students.

Achieving goals of equity requires carefully examining data on each and every student. One school we studied has long used a process by which teams of teachers sit down with the principal, a counselor, and 2–3 intervention teachers three times a year (fall, winter, and spring) to discuss data and plan instructional interventions for every student (Datnow and Park, 2019). At the spring meeting, the group also discussed classroom placements for the following year. A notable feature of these meetings, however, was that while meeting participants all had numeric data on student achievement in front of them, their discussion was not restricted to numbers. Most discussion focused on providing a full picture of the student beyond academic achievement and involved discussions of students' home lives, social adjustment, classroom behaviors, work habits, completion of homework and so forth, none of which were reflected on the data sheets. Wardrip and Herman (2017) also found that "Teachers framed students' instructional needs with information that fell outside of the data the school collected" (p. 14). In their study, knowing the students' "backstories" (e.g., their friends, aspirations, interests) provided a context by which educators reasoned about student data.

Examining data on all students also promotes shared responsibility, which is a key component of data use for equity. District and school leaders play an important role in cultivating a belief that teachers must share responsibility for all of the students at the school, not just those they have contact with in their classroom. Equity cannot be achieved unless data use efforts focus on all students. When data use is narrowly focused on students "on the bubble," many students get left behind. A focus on all students allows data use efforts to address students' individual needs and for instructional changes to focus on lifting the class as whole, rather than small groups of students. It also helps to promote and is supported by a shared sense of responsibility for all students.

Using data to confirm assumptions and using data to challenge beliefs

A goal of data driven decision making is to bring evidence to light that will help educators think about student achievement in a new way. However, examining data does not always lead to new interpretations. In a study of data use in Belgium, [Vanlommel et al. \(2017\)](#) found that “teachers seek for data that confirms what they believe to be true and avoid data that questions their beliefs” (p. 81). Data can be used to validate existing understandings of students’ learning profiles ([Oláh et al., 2010](#)). As [Oláh et al. \(2010\)](#) explain, teachers interpret data in the context of their expectations for individual students or for the class as a whole and rely on their background knowledge about students when interpreting data. When data do not fit with teachers’ expectations of students this can send up a “red flag” as one teacher in this study noted, which may turn out to be useful in addressing students’ learning needs.

However, when educators use student characteristics as explanations for results, they can reinforce a culture of low expectations and stereotypes ([Bertrand and Marsh, 2015](#)). For example, a teacher in Bertrand and Marsh’s study discussed data on her students such that “the connection between ‘resource kids’ and the lack of proficiency was self-evident, suggesting an assumption that students in special education score poorly on tests by nature” (p. 19). Moreover, this teacher attributed the assessment results to her students, not to her teaching. The attribution of results to what were thought to be stable student characteristics was a pattern in this study, and English learners, special education students, and other struggling students were “blamed” for outcomes.

When educators use data to confirm assumptions, this often goes hand-in-hand with comments about students’ home lives being the primary explanation for student achievement. When such assumptions are made, it is very difficult for educators to see data as a useful tool for improving their own practices, as they locate achievement patterns in the students’ backgrounds.

Paying close attention to teacher talk in the context of data collaboration meetings can help researchers examine how teachers think about student ability, as teachers often discuss data in relation to individual student achievement. In our own research ([Datnow et al., 2018](#)) and in [Bertrand and Marsh’s \(2015\)](#) study, the No Child Left Behind era accountability language figured strongly into teachers’ talk. Terms used to describe students such as “low,” “high,” or “below basic” are reinforced by assessment data showing which students were below, at, or above grade level. These labels are imposed upon teachers by broader policies for accountability and have become part of teachers’ lexicon. This lexicon appears to reify a hierarchy of ability and can constrain the ways in which teachers talk about student achievement and learning, as well as their expectations of students.

At the same time, data use has been shown to be a powerful tool to push teachers to challenge existing assumptions about student learning and to reflect critically on instructional practices ([Lachat and Smith, 2005](#)). The process of closely examining data in the context of teacher team meetings can facilitate teachers’ focus on student growth, thereby shaping teachers’ beliefs about what they think their students are capable of. The team meeting can provide a space and a routine for teachers to point to various forms of “data” when making claims about student achievement. For example, in our own work ([Park, 2018](#)), these opportunities for dialog around data helped teachers move away from deficit framing of students and toward discussions of student growth and potential. Coaches or other instructional leaders played a critical role in reframing conversations around student assets.

In the end, data can play a very powerful role in challenging stereotypes and providing an opportunity for educators to examine the relationship between instructional practices and achievement. But simply deciding to build professional learning communities is not sufficient to bring about change. As [Pollock \(2017\)](#) argued, school talk must debunk myths about intelligence as easily measurable and explicitly challenge common comments about young people or families that are harmful. Framing conversations carefully and providing the opportunity for educators to bring multiple sources to bear on conversations about student achievement are critical.

Using data for tracking and flexible grouping

Educators’ conceptions of student ability inform their logics about how to organize instruction for students. In a study of ten detracking schools, [Oakes et al. \(1997\)](#) found that some teachers held a conventional view of intelligence in which ability was seen as an uni-dimensional, fixed, and innate characteristic. This led them to believe that intelligence could be easily assessed and to support tracking and ability grouping. Beliefs that overlapped race with ability were also prevalent among this group. In contrast, another group of teachers believed intelligence was multidimensional and plastic, leading them to support mixed ability grouped classes ([Oakes et al., 1997](#), p. 494). Data have long been an important part of tracking practices in schools. The use of data starts early in the educational process as students are often assessed for school readiness in kindergarten and then move through the system at different speeds ([Oakes, 2005](#)). By high school, disproportionate percentages of African American and Latino students are in courses that include less rigorous instruction, less qualified teachers, fewer resources, and lower expectations than their white or Asian counterparts in higher track classes ([Oakes et al., 1992](#)). Thus, tracking has significant consequences for students’ opportunity to learn.

Just as data have been used in the past to justify tracking decisions, in recent years, educators have turned to benchmark assessments as a placement tool, which is not their intended purpose. Instead, these assessments are designed to provide educators with interim feedback on student progress relative to curriculum standards. This has been documented in numerous studies ([Davidson and Frohbieter, 2011](#); [Heppen et al., 2012](#); [Shepard et al., 2011](#)). In addition to misusing the assessments for unintended purposes, the sole use of benchmark assessments places too much emphasis on one form of data to make such a high-stakes decision.

Uncritical and high-stakes uses of data can have long-term consequences for students, whose confidence and access to rigorous instruction is often tied to the labels that are applied to them.

Whereas the use of data for tracking purposes limits student opportunities, the use of data for flexible grouping of students can help to expand opportunities. As part of their comprehensive, three-times a year data analysis process, educators at an elementary school we described earlier created language arts and spelling groups that shifted often (Datnow and Park, 2019). In another elementary school, teachers used formative assessment data daily to differentiate instruction and to place students in flexible learning groups to address particular skill areas. Along these lines, Oláh et al.'s (2010) study found that elementary school teachers used small, pullout group instruction during a designated re-teaching week. Based on results on a benchmark assessment, teachers determined the students of most need. As a teacher explained, "If it's half the class ... I'll just reteach the whole thing. But if it's a few children ... then I would definitely pull them out and get some special homework for them to work on" (Oláh et al., 2010, p. 240). High scoring students received less direct instruction during the re-teaching week and instead were given enrichment worksheets, games, or more time on the computer. This approach to flexible grouping based solely around remediation also has the unintended consequence of stigmatizing the students who are repeatedly "called to the back to table" to work with the teacher.

Overall, while we have observed instances in which data use has inspired flexible grouping geared around students' individual needs and skills, there is certainly a strong cautionary tale to be told about the connection between data use and student grouping. Problematic practices of tracking and ability grouping with long-term consequences continue to abound in schools and are legitimated with data. In fact, tracking remains one of the most enduring practices in American high schools, in spite of a robust research base denouncing it.

Conclusion

This chapter drew upon extant studies to examine the ways in which the data use practices in schools may serve to open or close doors for students. We explored tensions between accountability-driven data use and data use for continuous improvement, data use to confirm assumptions and data use to challenge beliefs, and the use of data for tracking and flexible grouping. These tensions are examined and discussed across the scholarship on data use. By synthesizing these tensions as broad sets of decisions, we contribute to research on how data use practices can promote equity.

These sets of decisions are not necessarily dualisms with dichotomous sets of practices. Rather, along each of these dimensions, there are active decision makers, complex processes of data use at play, and a great deal of variation both within and across contexts. These decisions are also intertwined and may need to be considered in relationship to one another. For example, the decision to challenge deficit beliefs about student abilities using data will not likely occur without a broader definition of what counts as data, especially beyond standardized assessments. Conversely, the decision to use multiple forms of data alone will not lead to a goal of expanding students' opportunities to learn, without the value for using data to challenge assumptions or building on students' assets. Educators and policymakers are faced with a set of critical choices in their work with data that can profoundly affect students' daily educational experiences and trajectories. Some of these choices are more likely to expand opportunities for students, whereas others are more likely to limit them. This especially true when there is a pattern of choices within a particular school.

When accountability frameworks dominate teacher conversations and instructional interventions are focused on students for whom schools will get the most "bang for the buck" on standardized measures, students are more likely to suffer. The curriculum in these schools is likely to be narrower, with student achievement primarily focused on single measure, which often disadvantages low-income, minority students. The use of data for tracking, long-term ability grouping, and placement is of particular concern, as it can serve to reinforce hierarchies among students. In schools where data are more often used to actively challenge stereotypes, to examine student growth as well as weaknesses, and to differentiate instruction in dynamic ways, students likely have more opportunities for success. Students are also more likely to thrive when educators share responsibility for their success.

Just as equity needs to be an explicit goal in data use practices, research on data use also needs an equity lens. Educational improvement and policy lenses tend to prioritize organizational changes associated with reforms. Although many educational researchers list equity as an important goal of school reform, this concern may not be central to their work. Putting equity at the center of studies of data use—and indeed all educational reforms—may involve the use of different research questions, methodologies and/or theoretical frameworks. It requires explicit attention to questions and issues raised in this article and in others. In what ways do data use lead to inequitable outcomes for differing groups of students and what are the specific data use conditions and processes that contribute to unequal or equal opportunities to learn? How do educators' assumptions, often tied to beliefs about students' backgrounds, become challenged or reified by data use? What data use practices support shifts away from deficit thinking and fixed beliefs about intelligence or ability? How do data-informed leaders with an explicit equity-orientation build a school culture that expands opportunities to learn not just for students but also for teachers?

This equity-centered agenda on data use also may involve assembling diverse teams of researchers, a willingness to engage in difficult conversations, and carefully framing findings to do justice to the complexity of equity-driven change. With data use efforts occurring in a wide range of settings across the globe, researchers have an unprecedented opportunity to further document ways in which data use opens or closes doors for students. Studying data use through an equity lens provides unique affordances that can help to eliminate problematic practices and promote better schooling for all.

Purpose: Keeping experienced and competent teachers in schools is becoming an important challenge for school leadership. Hence, this research explored an innovative relationship between principal's information-processing mechanisms (PIPMs) (as a school level variable that reflects school principals' ability to gather, assimilated and disseminate information), and a teacher's intent to leave his or her school (as the individual level variable).

Design/methodology/approach: Data were collected through a survey of 101 principals and 1130 teachers from 101 Jewish and Arab elementary schools randomly selected from the database of the Israeli education system. To test the proposed multilevel model, we conducted a multi-level SEM by the M-plus program in which individual responses are nested within organizational units (schools).

Findings: With controlling for principals' seniority and teachers' tenure in teaching, the relationship between the quality of leadership learning, as indicated by PIPMs, and teacher's intent to leave is significant and negative. The analysis confirms that PIPMs negatively predicts teacher's intent to leave.

Practical implications: Our findings point to principals' information processing as an important factor that contributes to a teacher's intent to leave, thus highlighting the role principal's leadership learning plays in teacher retention and how it can aid in reducing the phenomenon of teacher's intent to leave.

Originality/value: This study adds to the body of research directed at identifying school principals' learning processes, which may decrease a teacher's intent to leave and are amenable to leadership intervention.

Introduction

Organizational learning is vital to school performance, with schools that incorporate this approach shown to perform better (for example, [Mulford and Silins, 2011](#); [Qadach et al., 2020](#)). Such an approach entails the development of learning processes, strategies and structures geared toward a more effective response to changing, uncertain or dynamic circumstances ([Fauske and Raybould, 2005](#); [Giles and Hargreaves, 2006](#); [Kruse, 2003](#)). Adopting an organizational learning approach necessitates the establishment and nurturing of a framework for the continuous collective processing, understanding and application of knowledge about teaching and learning ([Louis, 2006](#); [Schechter, 2008](#)). In this chapter, we focus on the impact of school principals' learning in the context of their implementation of school principal's information processing mechanisms (PIPMs) on teacher's intent to leave.

The principal's role in teacher retention: teacher's intent to leave

Withdrawal behavior has been studied by looking at employees' responses to items concerning contemplating leaving and the desire and likelihood of quitting (Hanisch and Hulin, 1991). A teacher's intent to leave can be viewed as a form of withdrawal, that is, a set of attitudes and behaviors characteristic of workers who become less participative (Kaplan et al., 2009) or leave the job altogether (Rahim and Afza, 1993). Withdrawal behavior in teachers manifests itself as increased burnout and decreased motivation and organizational commitment (Conley and You, 2009), and lower work effort and productivity (Fore et al., 2002; Tett and Meyer, 1993). Consequently, much research in recent years has focused on identifying administrative support and work-related factors that can reduce a teacher's desire to leave.

Intent to leave is viewed as the extent to which workers seek alternative employment elsewhere (Shapira-Lishchinsky and Rosenblatt, 2009). Intent to leave is considered a contributing factor to reduced school effectiveness (Ingersoll, 2012; Shaw et al., 2005), teacher productivity and motivation, and overall school morale (Tett and Meyer, 1993).

Schools worldwide find it difficult to retain effective teachers, which entails considerable human resource management costs (Harris et al., 2005). More importantly, a teacher's intent to leave has unique organizational and pedagogical implications. Those seeking to leave are typically the more qualified teachers who are more likely to secure employment elsewhere. This jeopardizes the school's teaching standards and negatively impacts the motivation and effort of the remaining teachers in the school (Ingersoll, 2012; Josephson et al., 2008; Parry, 2008; Rosenblatt and Shirom, 2006). A teacher's intent to leave also increases the pressure on the remaining faculty (Torrez and Kritsonis, 2008), leading to a decline in morale, with additional staff potentially following suit (Shaw et al., 2005). It can also damage a school's reputation and teaching staff cohesion, which inevitably reduces the school's effectiveness (Ingersoll, 2012; Schaefer et al., 2012; Tett and Meyer, 1993). It is, therefore, vital to elucidate the reasons behind a teacher's decision to leave a school or the educational system altogether to reduce the scope of this negative phenomenon (Lopez, 2018).

Teachers contemplate quitting when they have little work satisfaction and consider leaving a low-risk act. The lack of professional opportunities, limited professional autonomy, unsatisfactory wages and poor job satisfaction all play a dominant role in considering to leave (Fochsen et al., 2005; Morrell, 2004; Zembylas and Papanastasiou, 2004).

As discussed earlier, an ever-growing body of literature affirms the key role principals play in improving school effectiveness and promoting change (for example, Da'as, 2019; Sun and Leithwood, 2017). It is particularly important when it comes to teacher retention (Cha and Cohen-Vogel, 2011; Hambrick, 2007). Research has linked leaders' actions to teacher job satisfaction, turnover and retention (Brown and Wynn, 2009; McCann et al., 2009). Other studies have linked teacher's perception of their school leaders and their intent to leave (Hughes et al., 2015; Qadach et al., 2019). Teachers' intent to leave was also inversely correlated with leadership supportive of an environment that allows teachers to exercise their potential as educators (Markow and Pieteres, 2009). In line, highly rated principals succeeded in retaining good teachers, with principal support an important factor in new teacher retention (Grissom and Loeb, 2011).

A recent important study in an elementary school shone a light on the negative correlation between the organizational learning climate and a teacher's intent to leave at the individual level ($\gamma = -0.14$, $p < 0.05$; Da'as et al., 2020). It likewise found a positive relationship between the innovative approach of a principal and organizational learning atmosphere ($\gamma = 0.30$, $p < 0.001$). Further, the study confirmed the mediation effect: the relationship between principals' innovative behavior and a teacher's intent to leave is mediated by the perceptions of the organizational learning climate. This previous study asserted that school principal behaviors and the learning climate that he or she designed can influence teacher's intent to leave on the individual level.

Our recent studies identified two other school-level variables that exhibit a direct, negative relationship with teacher's desire to leave: collective teacher efficacy (CTE) and shared vision (Qadach et al., 2019). Conversely, instructional leadership showed no such correlation. School culture, principal leadership (i.e., is supportive and creates school environments conducive to learning), and the collegial relationships are interrelated key elements that were found to improve the social context of work and predict teacher retention (Johnson et al., 2012). Teachers' perceptions of the school administration have by far the greatest influence on teacher retention decisions (Boyd et al., 2011). Further, Studies have shown that the quality of school leadership is a strong indicator of teacher retention (e.g., Boyd et al., 2011; Grissom, 2011; Ladd, 2011). This finding suggests that principals that succeed in creating a more positive school climates are likewise better able to retain teachers. This is because teachers receive greater support, more opportunities for professional growth, and more favorable working conditions, the outcome of which is greater job satisfaction and loyalty (Ingersoll, 2001; Johnson et al., 2012; Kraft et al., 2016).

A new approach to teacher retention has been coined *strategic retention*, denoting a differential approach whereby efforts are made both to retain effective teachers and to not retain ineffective ones (Grissom and Bartanen, 2019). For example, principals may seek to reduce the overall teacher turnover rate, but direct greater efforts toward their top teachers. Another strategy is to actively encourage turnover among low performers, through, for example, opting not to renew a contract, "counseling out" or making the job less palatable (Drake et al., 2016).

Previous findings indicated that teachers who believed their principal took an inclusive approach to leadership exhibited greater enthusiasm and commitment to their school. Conversely, teachers who considered their principal's approach to be instrumental, i.e., demanding compliance rather than including them in school decisions and processes, experienced frustration and an increased intent to leave the school (Johnson, et al., 2012).

Principals' support of school learning

Considering schools' complex, dynamic environment, where interconnected components must work together to ensure the continued high-performance of teachers (Ingersoll, 2012; Schaefer et al., 2012), it is imperative to investigate the way by which principals affect organizational features and processes and employee perceptions and attitudes. Previous studies indicate that teacher performance and classroom practices are all influenced by leadership attributes and behavior (for example, Louis et al., 2010). Sebastian et al. (2017) found that leadership affects learning indirectly by shaping conditions that promote effective teaching and learning. Louis et al. (2010) pointed to shared and instructional leadership as an indirect contributor to student achievements. Moreover, Day et al. (2016) founded that both transformational and instructional school principal leadership directly and indirectly promote schools', teachers' and students' success. These outcomes seem to be a result of the way teachers organize themselves into professional communities with strongly held norms and values, reflective discussions about instruction, and a sense of collective responsibility for student learning.

As those tasked with improving school performance, school principals also play a key role in organizational learning processes (Da'as et al., 2019; Davis, 2005; Desjardins and Donaldson, 2008; Drago-Severson and Pinto, 2009; Leithwood, 2004; Waters and Grubb, 2004). Charismatic leadership is conducive to a positive climate of organizational learning in the school, namely, its employees' attitudes toward the work setting's positive or negative impact on learning, and to the formation of trust among the teaching staff, which translates into school outcomes (according to superintendent and parent evaluation) (Berson et al., 2015).

In fact, the last decade has seen organizational learning become a major focus of school leaders. Among the driving forces for principal's support of this focus on organizational learning (AKA learning-centered schools) is the intricate socio-cultural milieu and policy accountability reforms (for example, Darling-Hammond et al., 2007; Drago-Severson, 2009). This has given rise to approaches such as "Learning-focused leadership" (Knapp and Feldman, 2012) or "learning-centered leadership" (Murphy, 2006), which deal with leaders' roles in student, professional, and system learning. Strong instructional leaders have been shown to form a shared vision (Hallinger and Wang, 2015), create a school culture (Heck and Hallinger, 2014), establish a positive instructional climate (May and Supovitz, 2011), enhance collective teacher efficacy (Qadach et al., 2019), and participate in curricular and instructional issues with their teaching staff (Hornig and Loeb, 2010).

To bring about organizational learning, the leader is tasked with overseeing collective learning processes and formulating a school-wide learning agenda (Knapp and Copland, 2006). According to Ash and Persall (2000), the principal is the chief learning officer, who is required to ensure the existence of a reward-based environment conducive to teacher leadership, collaboration and professional development. This necessitates principals to ensure that relevant knowledge is gathered and then appropriately shared among the teaching faculty and staff. Information gathering can be achieved through experiential learning, vicarious learning, recruiting new members, and searching and observing the environment. Experiential learning denotes intra-organizational experiments and self-appraisal. Vicarious learning entails learning from other organizations' strategies and technologies. In practical terms, principals need to constantly provide new information and opportunities for collaborative planning and learning and to set in place an environment that promotes leadership throughout the school (see also McGough, 2003). Leaders are accountable for arranging the interactive social environment and ensuring that adequate resources are available to support teacher learning (for example, Halverson et al., 2005). They also need to be capable of building strong professional communities that can foster teacher collaboration, dialogue, and learning (Fullan, 2009).

To form such a community, principals must rely on methodological research concerning the development of school learning, but tailor it to suit their school's particular characteristics and needs. In other words, they must adopt information-processing mechanisms that ensure efficient and well-targeted gathering and assimilation of information on changes occurring both within the school and in the community, complemented by effective means of the knowledge's analysis, storage and dissemination in an effort to advance the school's interests. This includes addressing social and political pressures while shielding their staff from detrimental policies, initiating school-improvement plans that align with external reforms, and catering to the needs of the school's students and community. Effort should also be directed to ensure ongoing learning, even when faced with counter social, political and economic forces. Collaborating with school community members can aid in determining the school's particular attributes that cannot be assessed via quantitative measurements that will ensure the school's ongoing success (Kochan et al., 2002). Organizational learning entails both extending one's gaze beyond the school grounds in search of learning opportunities and working within the school to develop professional learning communities (Knapp and Feldman, 2012). Particularly given the growing emphasis on accountability and standardization, principals must actively strive to realize a school culture that features both individual and collective learning (Desjardins and Donaldson, 2008; Drago-Severson and Pinto, 2009; Schlechty, 2009).

School principals' information processing mechanisms (PIPMs)

The great promise of learning-centered school systems is an improvement in student scholastic performance (Browne-Ferrigno, 2007; Fullan, 2009). This has led to principal accountability for teaching and learning issues (Orr, 2006), with the expectation that principals establish collective learning opportunities in elementary schools for both faculty and students, collectively referred to as "principals' information processing mechanisms" (PIPMs), an approach explored by Schechter and Qadach (2016). In simple terms, PIPMs is a data-gathering and processing approach that enables school principals to collect information about school and relevant external processes and use the data as a guide to inform their leadership decisions and practices. In order to elucidate the ways by which principals can improve structural and procedural school learning arrangements for assembling, assessing, storing,

disseminating, retrieving and employing school-related information, the Authors adopted an information-processing perspective, which is based on assembling and analyzing information from internal (organizational) and external (environmental) sources. This approach, outlined in detail in [Schechter and Qadach \(2016\)](#), led the Authors to define the following four-factor model, which best suited their empirical results and conceptual formulation (see [Appendix A](#)), which together provide an indication of the quality of principals' learning mechanisms:

1. *Information storage and retrieval* – the manner by which principals store personal and organizational experiences, code them into school memory, and access them to guide decision making and actions (for example, “I document meetings with the superintendent, municipal authority and/or parents”).
2. *Stakeholder information retrieval* – the manner by which principals attain information from students, parents, community members and superiors (for example, “I hold meetings with my superiors in order to learn from external events that affect the school”).
3. *Teacher information dissemination* – the manner by which principals convey information to school personnel for the purpose of collective analysis (for example, “I disseminate teachers' success stories among the staff”).
4. *External and internal information analysis* – the manner by which the school principal and teaching faculty discuss and analyze important events and/or useable data that affect the school, such as the school atmosphere and student academic performance (for example, “I examine external data [such as national exams] with the teaching staff”).

PIPMs support a learning-centered school approach by forming a central social platform for the formulation, analysis and sharing of knowledge and new standard routines and procedures and their dissemination to all the school's stakeholders ([Ellis and Shpilberg, 2003](#); [Lipshitz et al., 2002](#)). As noted by [Schechter and Qadach \(2016\)](#), the PIPM perspective is supported by the growing realization that most principal-assessment instruments focus on general management (for example, implementing vision) or traits rather than on the leaders' critical behaviors and actions within the learning-centered leadership framework ([Hitt and Tucker, 2016](#); [Leithwood and Sun, 2012](#)).

[Schechter and Qadach, \(2016\)](#) validated the four-factor model via constructing a PIPM questionnaire, which they then used to assess the correlation of the developed scale with established work-related constructs. [Schechter and Qadach \(2016\)](#) found PIPMs to positively and significantly correlate with teachers' organizational commitment, as well as with the three factors of instructional leadership (IL), namely, determining the school mission, overseeing the instructional program, and working toward a school atmosphere conducive of learning. All the PIPMs factors, except for “external and internal information analysis”, showed positive (moderate) and significant correlation with principal IL factors.

We also assessed PIPMs' influence on teacher's organizational commitment ([Schechter and Qadach, 2016](#)). Here, too, the entire PIPMs questionnaire moderately correlated with affective commitment, but not with normative or continuance commitment. These findings are in line with earlier studies that found affective commitment to be the most dominant determinant among the three commitments in terms of staff behavior ([Cohen, 2003](#); [Shapira-Lishchinsky and Rosenblatt, 2009](#)). Further, a recent study found that PIPM's directly and positively predicts school principal instructional leadership (IL), and the IL mediates the relationship between PIPM's and school Organizational Learning Mechanisms (OLM's) ([Qadach et al., 2020](#)).

In summary, the PIPM questionnaire had a notable, positive, moderate correlation with instructional leadership and teachers' affective commitment, but not with normative commitment or continuance commitment. Thus, the PIPM questionnaire is an efficient tool for principal evaluation of the effectiveness of various strategies for promoting learning-centered schools. It could further offer the means to self-monitor the contribution of the principal to disseminating organizational learning approaches and subsequently modifying the strategies to reach a more optimal balance between the various components ([Schechter and Qadach, 2016](#)). Information analysis actions, for example, could be balanced with information collection ones to provide information that aids the implementation of effective school initiatives.

School principal learning-centered leadership impact on teacher's intent to leave

A yet to be explored aspect of the principal's learning-centered leadership is to delineate what are the strategies, as reflected in PIPMs, that directly influences teacher retention. To investigate this issue, we applied PIPMs in the context of a teacher's intent to leave (see [Fig. 1](#)) with the goal of identifying principal learning-centered leadership variable that counteract a teacher's intent to leave that can be employed as a means of leadership intervention.

Method

Participants and procedures

We randomly selected 101 elementary schools from a school list on the Israeli educational system website (i.e., from all of Israel). In this study, 101 principals and 1130 teachers participated; the teachers were randomly selected from each school. The principals filled a questionnaire on PIPMs and demographic variables and the teachers completed a questionnaire regarding the intent to leave and demographic variables. School size was determined based on the number of teachers in the school; the average was 33 (SD = 11.42). We ensured a random sampling minimum of 30% of the teaching staff at

each school. The approval of the Israeli Ministry of Education and of each school was obtained prior to administering the questionnaire.

The principals' average tenure in their job was 9.20 years ($SD = 7.01$). Ninety one percent of the teachers were women, and their average number of teaching years was 21.0 ($SD = 8.19$); 26% had a B.A. degree, and 67% an M.A. degree.

Measures

PIPMs

We used a questionnaire developed by [Schechter and Qadach \(2016\)](#), which included 22 items. Each principal was asked to complete one questionnaire. The principals rated the items on a 5-point Likert scale, ranging from *never* (1) to *always* (5). The questionnaire addressed four components ([Fig. 1](#)): (i) Receiving information (eight items), for example, "I meet with students in order to get exposed to difficulties, special requests, comments and insights," with an Alpha Cronbach of 0.84. (ii) Storing and retrieving information (five items), for example, "I document meetings with the superintendent, municipal authorities, and parents," with an Alpha reliability of 0.79. (iii) Analyzing external and internal information (four items), for example, "I examine external data (such as national exams) with the teaching staff," with an Alpha reliability of 0.80. (iv) Disseminating information to teachers (five items), for example, "I disseminate reports concerning professional changes and innovations among the staff," with an Alpha Cronbach of 0.81. Construct validity for PIPMs was measured by confirmatory factor analysis, using the AMOS program. The data fit the model, with a comparative fit index (CFI) of 0.90 and a root mean square error of approximation (RMSEA) of 0.06. We considered school principals' information processing mechanisms to be a unified construct affecting all members of a unit ([Kark et al., 2003](#)). Thus, an individual principals' PIPM score PIPMs was considered an organizational construct that reflects the school level.

Teacher's intent to leave

Teachers completed the 5-item intent-to-leave subscale of the [Shapira-Lishchinsky \(2012\)](#) survey. Each teacher was asked to complete one survey. Teachers rated items, such as "I'm considering contacting professional bodies about other work options," on a 5-point Likert scale, ranging from *strongly disagree* (1) to *strongly agree* (5), with an Alpha Cronbach of 0.88. The CFA results indicated good fit indices: $\chi^2 (5) = 29.47$, RMSEA = 0.05, CFI = 0.96, TLI = 0.94, IFI = 0.95.

Control variables

We controlled for the effects of principals' tenure in their job and teachers' years of teaching, variables that have been shown to be potentially relevant to school processes and outcomes (for example, [Qadach et al., 2020](#)).

Results

The data collected reflect a hierarchical structure in which individual responses are nested within organizational units (schools) ([Qadach et al., 2020](#), p. 14). Thus, we conducted multi-level structural equation modeling by the M-plus program ([Muthén and Muthén, 1998](#)). Our results indicate a good fit between the model ([Fig. 1](#)) and the data (CFI = 0.98; RMSEA = 0.05). As seen in

Fig. 1 Standardized path coefficients from principals to teacher's intent to leave ($N = 103$); $*** p < 0.001$; $* p < 0.05$

Fig. 1, with controlling for principals' seniority and teachers' tenure in teaching, the relationship between PIPMs and teacher's intent to leave is significant and negative ($\gamma = -0.18, p < 0.05$). In other words, once the effect of principal seniority as well as teacher seniority variables are controlled, there is a statistically significant negative relationship between principal learning-centered actions (PIPM'S) and the tendency of a teacher to leave the profession. A school principal learning-focused leadership through the assimilation of PIPMS mitigates this intent.

Discussion

This study adds to the limited existing research that found that teachers who are more likely to leave the profession are less likely to have a principal who creates a learning-centered environment that helps them exercise their potential as teachers (Markow and Pieteres, 2009). It further indicates that highly rated principals are successful in keeping high-performing teachers (Grissom and Loeb, 2011). Thus, as teachers who intend to leave often exhibit increased burnout and decreased motivation and organizational commitment (Conley and You, 2009), this study adds to the body of research directed at identifying the power and impact of PIPMs as a learning leader for the school teachers, which may decrease a teacher's intent to leave. These results are aligned with previous research that found that school principals' innovative behavior promotes an Organizational Learning Climate (OLC), which, in turn, negatively impacts teachers' intent to leave in the Israeli education system (Da'as et al., 2020).

School learning is critical to realizing school effectiveness. This is because schools that operate as learning organizations perform better than schools that do not (Da'as and Qadach, 2018). Furthermore, PIPMs, which offers school principals daily opportunities to share and evaluate information regarding their practices as a means to improve them further, was shown to significantly decrease a teacher's intent to leave. The PIPM learning processes, strategies and structures strengthen a principal's ability to respond in an effective manner to complex and dynamic situations, which inevitably affect teacher behaviors at the individual level, and, in line, a teacher's intention to leave. This study, therefore, adds to the ongoing efforts to find proxies and links between organizational-level and individual-level factors in the intricate workings of the school system (Da'as et al., 2019).

While limited research has been conducted on the relationship between PIPMs and a teacher's intent to leave, this study suggests a new theoretical contribution by confirming the negative correlations between the two variables. This emphasizes the significant role of PIPMs in schools, which according to our current results is a key predictor of future teacher behavior. In other words, when school principal PIPMs are implemented and the school organization enjoys the fruits of the learning added value, this will possibly decrease a teacher's intent to leave the school (Richardson et al., 2008). This study adds to the limited existing research directed at identifying school principal factors that decrease a teacher's intent to leave.

It is reasonable to assume that leaders provide their teachers with a supportive environment that allows them to expand their learning capacity, lead, and work together to improve their students' achievements (Seaton et al., 2008). As proposed by Printy (2008), leaders both set the agenda for teacher learning and school improvement and serve as brokers of knowledge and providers of resources in support of teacher learning and innovation initiatives. And setting the agenda for teacher learning (Printy, 2008), by way of modeling their learning (PIPMs) to teachers, most likely further promotes organizational learning and teacher cooperation (for example, information sharing) and work motivation. This, in turn, should reduce the likelihood that teachers will consider leaving their school, work or profession.

Principals who rely more heavily on PIPM processes may also elicit stronger appreciation from their teaching staff, which is probably based more on emotional attachment than a sense of obligation. The outcome may be a greater willingness of teachers to get involved and invest time in formal and informal activities in an effort to achieve the school's mission. Our findings indicate that principals that effectively operate PIPMs will be rewarded with heightened teacher affective commitment (Schechter and Qadach, 2016), and with it, a lower likelihood of teachers leaving the school.

In summary, in this complex educational leadership context, we argue that, in order to decrease a teacher's intent to leave, in line with the PIMP model, school leaders need to receive, store and retrieve information, think and plan strategically, analyze external and internal information, so as to make decisions effectively, disseminate information to teachers, and communicate effectively with teachers and promote their emotional well-being.

Practical implications

Our study's findings are important for policy-makers and for school superintendents, both of whom are responsible for training principals. Leadership programs should consider focusing on helping principals develop and promote PIPMs. In this regard, the nature of the interface between the principals' contribution to organizational learning in schools must be assessed, especially those exchanges that either foster or hamper the principals' efforts to adopt information processing mechanisms to decrease teachers' intent to leave.

Further, the results highlight the pivotal role of school principal learning in helping determine teacher's withdrawal behavior. Day-to-day principal concerns often preclude teams and organizations from investing in learning activities. We, therefore, propose to design organizational mechanisms or systems (OLMs) that continually address learning. For example, ongoing team meetings

could be devoted to analyzing, seeking, sharing and disseminating information as mechanisms for learning schools (Qadach et al., 2020).

This study also has important implications in the educational realm, specifically for policies concerning public school administration. Principals face the challenge of boosting school performance, and facilitating a climate of organizational learning may provide them with an effective means to do so. Our findings suggest that a principal's learning processes may be the key to effective processes in schools.

Appendix: PIPM questionnaire

Factor 1: storing and retrieving information

I direct the staff to catalog learning materials for the students.

I document meetings with the superintendent, municipal authority, or the parents.

For evaluation purposes, I encourage the use of previous reports dealing with learning and teaching.

I maintain meeting protocols.

I make use of databases of teacher data (evaluation reports, absences, achievements) in decision making.

Factor 2: receiving information from students, parents, the community, and superiors

I meet with community representatives to promote school needs.

I hold meetings with my superiors in order to learn from external events that affect the school.

I examine external evaluation data together with the local authority.

I meet with representatives of the PTA in order to receive feedback about school affairs.

I meet with students in order to get exposed to difficulties, special requests, comments and insights.

I participate in professional development programs for principals.

I meet with parents in order to get exposed to difficulties, special requests, comments and insights.

I examine external evaluation data with the superintendent.

Factor 3: disseminating information to teachers

I disseminate among the staff reports concerning professional changes and innovations.

I help teachers share their special ideas with other teachers in the school.

I disseminate teachers' successes among the staff.

I disseminate the district publications and ministry circulars among the staff.

Factor 4: analyzing external and internal information

I hold meetings with the teaching staff in order to examine information about external events that affect the school.

I examine external data (such as national exams) with the teaching staff.

I initiate and participate in teaching staff meetings in order to evaluate the school climate.

I initiate and participate in teaching staff meetings in order to evaluate student academic achievements.

I observe teachers' lessons.

Introduction

In addition to the moral obligation to prepare the youth under their care for success in post-secondary education or careers in increasingly competitive and highly skilled workforces, educational leaders and policymakers around the world face an intensifying demand for increased student academic outcomes. These pressures are exacerbated by factors such as shrinking global markets, the use of standardized tests for national comparisons, the proliferation of alternatives to traditional public schools and a lack of public trust in education. The overwhelming political and economic response to these pressures has been grounded in neoliberalism, the notion that economic and education policy can enable more efficient education systems through open market competition, standardization and high-stakes testing (Butler, 2014). Furthermore, this perspective has engendered an accountability context in which teachers, leaders and policymakers are held responsible for student success (Zepeda et al., 2017).

Meeting the demand for increased academic outcomes is challenging for all educators. Yet, realizing these outcomes is more challenging in some schools than in others. The climate of accountability for higher educational outcomes has led to a focus on schools with low levels of academic performance on standardized tests and other outcomes, such as graduation rates. The conditions that can negatively influence these indicators of success, not surprisingly, are those that undermine teaching and learning practices. These conditions include economic, political, historical, geographic, socio-economic and environmental factors, which can also exacerbate the disparities between schools' abilities to provide equitable educational opportunities for students.

Student academic outcomes are viewed as the collective responsibility of educators at multiple levels in Organization for Economic Cooperation and Development (OECD) countries (Pont, 2020). However, given the vast body of research on the influence of school leaders on student learning outcomes and the tendency to hold formally recognized leaders responsible for these outcomes, for the purpose of this article, I focus on the role of the singular school leader. Yet, I do so with the understanding that successful leaders enlist and enable other leaders in meeting the learning needs of their students. Furthermore, I use the term school leader throughout the article rather than principal as the term for the sole, formally recognized leader of a school varies in different regions of the world and can include headmaster, head teacher and director among others (see Pont, 2020).

Viewing schools where educators encounter greater than usual challenges meeting the social, emotional and academic needs of their students as high needs schools, and considering the key role of school leaders in meeting these challenges, in the following sections of this article I describe the characteristics of high needs schools, effective school leadership practices and leadership practices that are particularly effective in high needs schools. In describing the effective practices of leaders in high needs schools, I focus on three integrated and mutually reinforcing strategies: taking a contextually relevant approach, increasing organizational capacity and leading collaborative and continuous school-wide improvement efforts. Finally, given the limited attention to the development of leaders for high needs schools (Lochmiller and Chesnut, 2016), I conclude the article by discussing strategies for preparing and supporting leaders for such schools.

High needs schools

The phrase high needs is usually attributed to those schools in which educators find it more challenging to realize high levels of academic outcomes for their students. Indeed, in the previous edition of this encyclopedia, Harris (2010) referred to such schools

as “challenging” (p. 778). The phrase high needs schools often conjures up images of inner city or rural schools situated in economically depressed locations. Some organizations in the United States, in fact, use poverty to classify schools as high needs. This classification is typically based on the percentage of students eligible to receive free or reduced-priced meals at school under the National School Lunch Program (NLSP). For instance, the Teacher Quality Act (2002) defined high needs elementary schools as those in which 60% of students are eligible for free or reduced-price meals. Use of this proxy for poverty levels is consistent with a report by the [Mid-Continent Research for Education and Learning \(2005\)](#), which defined high needs elementary schools as those in which at least 50% of students were eligible for free or reduced-priced meals. According to the National Center for Educational Statistics (NCES), in 2016 at least 50% of students were eligible for FRPL in at least 50% of public schools in the United States ([NCES, 2018](#)).

Characterizing high needs schools

Though poverty is a factor in a large percentage of public schools in the United States, racial and ethnic groups are not equally distributed among high poverty schools. Schools that serve higher percentages of students from low income households also tend to have higher concentrations of students who are non-white and do not speak English as a first language ([Musu-Gillette et al., 2017](#); [NCES, 2018](#)). Given the well-documented and negative influences of poverty on student learning outcomes ([Berliner, 2009](#); [Lacour and Tissington, 2011](#)), the disparities in educational funding ([EdBuild, 2019](#)) and the persistent achievement gap between white and non-white students ([Musu-Gillette et al., 2017](#)), it is imperative that leaders in high needs schools understand the historical, political, social and cultural norms that create and maintain these conditions ([Berry et al., 2019](#)). In addition, these leaders need to meet the demands of accountability policies while developing a collective vision that transcends the immediate teaching and learning challenges to focus instead on marshalling a sustained commitment to meeting the learning needs of all students.

Despite poverty often serving as the defining characteristic of high needs schools, other characteristics also warrant consideration. These aspects can include those that relate specifically to physical, financial, political, human and environmental factors. ([Baran and Berry, 2015](#); [Murakami et al., 2019](#)). These factors can be seen in many rural schools, with their smaller population centers and long distances from developed areas. Remoteness, an aging population ([Argent, 2016](#)) and high levels of poverty ([Showalter et al., 2019](#)) can lead to fewer resources being generated by local tax bases to support school initiatives. This lack of resources can in turn hinder a school leader’s ability to fund adequate instructional programs and recruit effective teachers ([Wieczorek and Manard, 2018](#)).

Recruiting and retaining effective teachers has been identified as a particular challenge for rural schools in multiple studies. A study of the teaching force in the United States over the last three decades ([Ingersoll et al., 2018](#)), a study of rural Australian schools ([Downes and Roberts, 2018](#)) and a study of rural schools in Australia, Canada and New Zealand ([Sullivan et al., 2018](#)) all indicated that rural schools had the highest teacher turnover rates. The higher level of teacher turnover in rural schools is further exacerbated by higher levels of school leader turnover ([Hansen, 2018](#); [Pendola and Fuller, 2018](#)). Furthermore, the higher rate of teacher and leader turnover in rural and high poverty schools negatively impacts student learning outcomes ([Bêteille et al., 2012](#)) and leads to greater inequities between rural and non-rural students ([Sullivan et al., 2018](#)).

Additionally, the messages students in high needs schools receive about themselves, their schools and their generally lower levels of academic achievement can have a negative influence on their social and emotional development. Over time, these messages can become internalized and detrimentally impact students’ educational aspirations ([Byun et al., 2012](#)). Thus, leaders of high needs schools need to attend to students’ social and emotional needs as well as their academic ones.

Resources for high needs schools

Educational leaders and policymakers around the world are tasked with meeting the demand for increased academic outcomes in schools. Increasingly common approaches to meeting this demand being adopted in Australia, Canada, the US and some European countries are grounded in the neoliberal philosophies that emanated from the UK and the US in the 1980s ([Sahlberg, 2016](#)). Though some countries in Europe, East Asia and elsewhere have resisted such approaches to educational reform, the trend toward competition, standardization and high-stakes testing is expanding across the globe ([Sahlberg, 2016](#)). Policymakers in the United States have attempted to redress the conditions that contribute to lower levels of academic outcomes in high needs schools with a combination of accountability demands, resource allocations and, more recently, greater flexibility for how resources are employed. This balance of accountability, resources and flexibility can be seen in the [Every Student Succeeds Act \(ESSA\) \(2015\)](#), the most recent re-authorization of the [Elementary and Secondary Education Act \(ESEA\) \(1965\)](#). This balance is most apparent in ESSA’s aims “to require states to align their education programs with college and career ready standards and to extend the federal focus on equity by providing resources for poor students, students of color, English language learners, and students with disabilities” ([Young et al., 2017](#), p. 706).

The most prominent avenue for distributing federal money to local education agencies is through Title I, Part A of ESSA. Title I money, as it is commonly referred, is intended to fund schoolwide programs and supplemental instruction that can aid in raising the academic outcomes of low achieving students in schools where at least 40% of students are from low-income families. In the 2015–16 school year, more than 26 million students studied in nearly 56,000 Title I schools ([U.S. Department of Education, 2018](#)).

Under ESSA, states are required to submit plans for meeting the challenges of high needs schools. In the US state of South Carolina, the state department of education created a school improvement framework that includes three programs focused on

improving the educational outcomes of high poverty and low performing schools (South Carolina Department of Education, 2017). Through these programs, schools receive differentiated levels of comprehensive and targeted grant money and other supports to facilitate school improvement efforts. Another example of state level support for schools in the state of South Carolina is the Rural Recruitment Initiative (Center for Educator Recruitment, Retention and Advancement (CERRA), 2017). Through this incentive program, administered by CERRA, resources are provided to rural and underserved districts with an annual teacher turnover rate of more than 11%. The resources provided by the initiative include incentives such as financial assistance or supplements to attract and retain teachers.

In addition to resources provided by state and federal authorities to assist in meeting academic outcomes in high needs schools, school leaders can also take advantage of resources within their local communities. Bauch (2001) viewed businesses, parent groups and religious and other community-based organizations as potential assets with which schools can form partnerships. Through such partnerships, Bauch suggested, students can learn more about the historical, geographic and cultural assets in their communities. Bauch also stated that these interactions between students and community members can enhance mutual interests and levels of commitment. Similarly, Green described how school leaders can use geographic information systems (GIS) technology (2015) and community-based equity audits (2017) to identify and map community assets in what are often considered low-opportunity communities.

As described in this section, high needs schools are typically characterized on the basis of poverty levels and are associated with high concentrations of minoritized students and low levels of academic achievement. However, for the purpose of understanding how school leaders can meet the challenges of teaching and learning in these schools, I have chosen to more broadly conceptualize high needs schools as those in which teachers and leaders encounter greater than usual challenges meeting the social, emotional and academic needs of their students. I have chosen this approach to avoid a focus on deficits which often position students and their communities as the source of the problem. Rather, in the following sections, I focus on how school leaders can marshal the resources and will to provide students in high needs schools with equitable learning opportunities.

Effective school leadership

Successful leadership in high needs schools is enacted by leaders who create and sustain teaching and learning conditions that meet the needs of their students and satisfy the demands of their accountability contexts. Though the quality of classroom instruction is the most significant school level factor in realizing academic outcomes, school leadership practices comprise the second most significant factor (Louis et al., 2010). Indeed, that leadership is a key factor in successful schools is widely accepted as can be seen in education policy in the US (Herman et al., 2017; Young et al., 2017) and other OECD countries (Pont, 2020). School leaders' significant if indirect effects on student learning outcomes are primarily associated with their roles in exerting leadership that fosters and sustains teaching and learning environments (Louis et al., 2010; Zepeda et al., 2017).

The research basis for this focus on school leadership is often attributed to the effective schools movement (Edmonds, 1979; Levine and Lezotte, 1990). The studies conducted as part of this effort were largely based in high-poverty urban schools where students were performing at higher than expected levels. Seeking to discover the correlates of success in these schools, scholars identified a number of leadership practices, including establishing a clear mission, high expectations, a safe environment and a strong focus on instruction (Edmonds, 1979; Levine and Lezotte, 1990). This focus on instruction was further buoyed by the work of Hallinger and Murphy (1986) who identified three primary tasks of instructional leadership: define the mission, manage the instructional program and promote the school climate.

Since this period, both instructional leadership, with its focus on improving classroom instruction (Hallinger, 2005), and transformational leadership, with its broader focus on creating a positive school environment (Leithwood and Jantzi, 2005), have been widely studied as part of an effort to inform and enhance school leadership practice. After completing a meta-analysis of effective school and leadership studies conducted over three decades, Leithwood and Riehl (2005) identified a combination of core instructional and transformational leadership practices they described as necessary but not sufficient for school effectiveness. These practices-setting directions, developing people, redesigning the organization and managing the instructional program-have been widely cited and have served as the building block of numerous educational leadership studies.

In a more recent study on the influence of school leadership on student learning outcomes, Leithwood et al. (2019) found that school leaders can enact the core leadership practices in four different paths, or categories of mediators, to influence student learning outcomes. The four paths include the rational, emotional, organizational and family path. The authors found that school leaders could most significantly influence student learning outcomes by improving variables on the rational path, which is "rooted in the knowledge and skills of school staff members about curriculum, teaching, and learning" (p. 5) and includes classroom instruction, academic press, disciplinary climate and teachers' use of instructional time. The findings from this study not only reinforced the benefits of combining instructional and transformational leadership practices but also emphasized the critical nature of those practices related to teaching and learning and their influence on student learning outcomes.

Research in the area of school leader effectiveness has also emphasized the need to adapt leadership practices to suit immediate contexts (Hallinger, 2011; Leithwood et al., 2008; Louis et al., 2010). As Leithwood et al. (2019) noted in the conclusion of their study, school leaders have to make choices regarding which strategies to use when and how with little guidance from the research field. Given the dynamic challenges of high needs schools, the ability to enact practice in contextually relevant ways is essential (Klar and Huggins, 2020).

Effective leadership for high needs schools

The findings that emerged from the effective schools movement and many of the subsequent studies on effective school leadership were in fact generated in high needs schools. As such, it is important to acknowledge that what is today widely recognized as effective leadership is not only applicable to most schools but is in fact largely based on what is known about effective leadership in high needs schools. Building on this sound research basis, in the following section, I examine more closely three leadership practices that have been shown to be particularly effective in high needs schools: taking a contextually relevant approach, building organizational capacity and leading collaborative and continuous improvement efforts.

Taking a contextually relevant approach

As conceptualized in this article, educators in high needs schools face greater than usual challenges meeting the social, emotional and academic needs of their students. Yet, the needs of each high needs school are unique and require a unique set of strategies. That context influences teaching and learning conditions, and thus leadership practice, is widely recognized in the literature on effective school leadership. Some of the contextual factors that enable and constrain leadership practice include the community, cultural, economic, organizational and political contexts (Bredeson et al., 2011; Hallinger, 2018; Klar and Brewer, 2013). Also widely recognized, as noted previously, is the need to adapt leadership practices to suit these contextual circumstances (Clarke and O'Donoghue, 2017; Gurr and Drysdale, 2018; Hallinger, 2018; Okilwa and Barnett, 2018; Pashiardis et al., 2018). In a comparative study of successful school superintendents in Sweden and the United States, Bredeson et al. (2011) found that these leaders drew on a range of knowledge, skills and dispositions rather than relying on pre-determined leadership styles to lead in ways that were context-responsive, or contextually relevant (Klar and Huggins, 2020). Additionally, instead of merely addressing their unique contextual challenges reactively, these leaders also pushed back and shaped their contexts in ways that positively influenced the teaching and learning conditions in their schools.

The findings from these studies on district-level leaders' contextually relevant practices were echoed in a review of research studies on school leaders conducted as part of the International School Leadership Development Network (ISLDN). The ISLDN is a joint venture between the British Educational Leadership, Management and Administration Society and the University Council for Educational Administration (Baran and Berry, 2015). ISLDN members from over 20 countries have conducted international comparisons of effective leaders in high needs schools for nearly 10 years. As noted in Gur and Drysdale's (2018) review of this research, successful school leaders are not victims of their contextual circumstances, rather, as Bredeson et al. (2011) reported, they are able to push back and shape the influences of context on their schools.

A contextually relevant leadership approach requires a high level of understanding of the contextual factors positively and negatively influencing the educational environment. Bredeson and Klar (2008) described this understanding as contextual literacy, or the awareness of key aspects of a particular context, how those aspects influence and are influenced by each other and how they can be leveraged to achieve organizational goals. To better understand how leaders develop their contextual literacy, Bredeson and Klar developed a framework that includes five intersecting sources of their knowledge, skills and dispositions. This framework (people, personalization, place, professional knowledge and purpose) has since been used to study effective leaders in high needs rural schools (Klar et al., 2019b; Klar and Huggins, 2020).

In these studies, leaders demonstrated the need to work with and through people, develop trusting relationships and meet others' personal and professional needs while holding them to high expectations. The leaders personalized their roles by drawing on their own sets of unique skills, values, experiences and perspectives to initiate and model change. They displayed a sound understanding of the place and time in which their schools were situated, including the historical, geographic and economic influences and cultural norms of their settings. The leaders utilized their professional knowledge about teaching, and the resources, policies and practices that supported or limited the creation of effective learning environments to support and sustain change. Lastly, they were guided by a strong sense of purpose which positioned students at the center of decision making, was widely communicated and confronted deficit thinking wherever it occurred. Though this framework provides some insight into how school and district leaders develop the contextual literacy to lead in contextually relevant ways, as noted by Leithwood et al. (2019), more research is required to determine when and how school leaders focus their improvement efforts.

Though understanding and adapting leadership practices to suit a school's unique context is critical to successful student learning outcomes in all schools, it is particularly important in high needs schools. This distinction is due to the very challenges that characterize schools as being high needs. That is, the greater-than-average challenges of realizing high levels of student learning outcomes that accountability systems demand of all schools require unique approaches. Yet, the creativity, risk-taking and personalizing of the learning environment required to meet the needs of students in an environment characterized by higher levels of poverty and other political, socio-economic and historical stressors are challenging to develop (Berry et al., 2019), especially when educators are incentivized to narrow the curriculum to align with standardized accountability measures (Sahlberg, 2016). Thus, understanding how contextual factors positively and negatively influence their schools and how they can reshape the factors to ensure positive teaching and learning environments while also meeting their accountability demands requires leaders of high needs schools to possess a greater-than average focus on contextually relevant leadership practices.

Increasing organizational capacity

Despite the pressures for immediate changes in academic outcomes, successful leaders in high needs schools resist the temptation to grasp at quick fixes. Instead, they work to build the capacity of their schools to support and sustain appropriate teaching and learning activities. Given the indirect manner in which school leaders are able to enhance student learning outcomes through their support of teaching and learning activities (Leithwood et al., 2019; Robinson et al., 2008), it is essential that leaders in high needs schools focus on developing and sustaining effective teaching practices as a high priority and with a relentless focus (Harris, 2010).

The process of building capacity within any school involves increasing the motivation, resilience and other conditions necessary to sustain continuous learning efforts (Stoll and Bolam, 2005). The multiple aspects of building capacity can be seen in the core instructional and transformational leadership practices identified by Leithwood and Riehl (2005) and in Hallinger's (2011) review of decades of research on effective school leadership, from which he derived a model of leadership for learning. Like Leithwood and Riehl (2005), Hallinger (2011) recognized that leaders contribute to learning through multiple dimensions, which include having a vision for the future, developing processes that enhance academic outcomes and fostering the development of teachers and other leaders to assist in creating and maintaining effective policies and practices.

However, as Cohen et al. (2007) and Cohen et al. (2017) noted, there is a dilemma regarding education policies and practice. This dilemma is that policymakers rely on educators to solve problems, but the educators who have the problem are relying on the policymakers for solutions. Furthermore, Cohen et al. (2007) suggested that a school's level of extant capacity is relative to the amount of change required to meet the aims of a particular initiative. As this dilemma suggests, universal approaches to capacity building are unlikely to be successful. Rather, school leaders must work to draw upon and develop their contextual understanding to determine when and how to enact capacity building strategies in accordance with the scope of change required.

In addition, the work of capacity building requires a systemic focus on developing organizational learning rather than a singular focus on individuals or programs. Organizational learning is the school's collective ability to meet its teaching and learning challenges (Mulford and Silins, 2003) and provides an avenue to improving classroom instruction (Spillane and Louis, 2005). In high needs schools with high levels of organizational learning, members of the school community are able to assess and respond to challenges in ways that can lead to sustainable improvement. In their review of effective school leadership in rural high needs schools, Klar and Huggins (2020) developed a framework for understanding organizational learning. Building on the work of Mitchell and Sackney (2011) and Gurr and Drysdale (2007), the framework suggests that school leaders can foster organizational learning through a combination of developing the individual capacities of teachers and other staff, the abilities of people to collaborate, the organizational structures for these interactions to occur and the school's connections with families and other community based resources that could benefit students.

Building organizational capacity to respond to teaching and learning challenges is a key approach for any school leader. However, building the capacity of a school to meet these challenges is more difficult in high needs schools. One particularly important factor, given the importance of classroom instruction, is the higher level of teacher turnover in schools situated in low-income rural and urban communities (Ingersoll et al., 2018). This trend results in students in high needs schools receiving instruction from greater numbers of inexperienced teachers and illustrates the critical need for leaders of such schools to focus on building instructional capacity. Furthermore, given that the poorer working conditions often found in high needs schools are among the most common reasons teachers provide for leaving the profession (Ingersoll et al., 2018), leaders in high needs schools need to work to enhance the teaching and learning conditions. This can be done in part by developing or modifying organizational structures to create collaborative cultures (Louis et al., 2010), enable greater levels of individual and group learning (Mitchell and Sackney, 2011) and increase social interaction among teachers (Moolenaar, 2012).

Leading collaborative and continuous school-wide improvement efforts

In the United States, there has been a particularly intense focus on improving perennially low performing schools over the last two decades. Beginning with the *No Child Left Behind Act* (2001) and continuing through other initiatives, such as *Race to the Top* (2009), this focus has been on turning around low performing schools (Duke, 2012, 2014). Like its predecessors, ESSA has kept a focus on improving low performing schools. Though ESSA has provided more flexibility in achieving these aims, it also requires states and school districts to provide evidence of effectiveness through research-based interventions and school improvement planning processes (Sparks, 2018).

This focus on planning and data use to monitor progress in student learning outcomes runs counter to the urge to adopt quick fixes in the belief that long-struggling schools can be quickly improved simply by adopting new programs (Rohanna, 2017). Instead, there has been an increase in systemic and sustainable change efforts informed by the use of continuous school improvement processes (Sparks, 2018). The term continuous improvement describes the process of addressing problems of practice by using evidence and systematic approaches to improve systemic practices (Park et al., 2013; Sparks, 2018; Tichnor-Wagner et al., 2017).

Continuous improvement is closely aligned with improvement science, a disciplined approach to improving practice through inquiry (Bryk et al., 2015). Such inquiries often take the form of small-scale changes using models such as *Plan Do Study Act* (Langley et al., 2009; Park et al., 2013) and action research (Logan, 2014). In both cases, individuals or teams may investigate a problem of practice using disciplined inquiry, local practitioner knowledge and research to implement and study the effects of interventions. Based on the results of the intervention, the cycle may be continued, potentially resulting in deeper and broader levels of change. Bryk et al. (2015) described this approach to school improvement as accelerating "learning by doing" (p. 8).

Adopting an improvement science approach to school improvement allows leaders of high needs schools in particular to effectively and rapidly enhance their schools' individual and organizational capacities to address the misalignments within their systems. Studies of leaders in high needs schools implementing action research (Andreoli et al., 2019; Klar and Huggins, 2020) and PDSA cycles (Andreoli and Klar, 2020) highlight the benefits continuous improvement can bring to school improvement processes. These benefits include a deeper understanding of the assets and challenges related to problems, a more systematic and reflective approach to identifying and addressing challenges and an increase in the involvement, commitment and leadership of other teachers and administrators in meeting schools' teaching and learning needs.

In a recent study of a high needs, rural elementary school, Andreoli and Klar (2020) found that the principal and leadership team members collaboratively completing a continuous improvement inquiry cycle significantly enhanced their ability to learn by doing (Bryk et al., 2015). In this case, the school leaders use of the school improvement process led to more effectively utilizing data and prioritizing improvement strategies, incorporating multiple perspectives into problem-solving efforts and establishing a culture of risk-taking and ownership of teaching and learning practices. Combined, these strategies allowed these leaders to become the drivers of their own change processes and resulted in them significantly improving their ability to meet the needs of their students.

Combining contextual relevance, capacity building, and continuous improvement

Though described separately, the three practices explained in this section are both interconnected and mutually reinforcing. Combined, they can result in the development of schools and communities that are committed to and capable of meeting the social, emotional and academic needs of their students. This combination of approaches highlights the benefits of a systems perspective, which includes seeing both the parts and the whole rather than focusing on isolated components of systems (Shaked and Schechter, 2014).

As conceptualized in this article, educators in high needs schools have greater than usual challenges meeting the learning needs of their students. Effective leaders in high needs schools draw on their contextual awareness to focus their capacity building and continuous improvement efforts in ways that align with their unique contexts. Furthermore, as meeting the demands of accountability in organizations as dynamic as high needs schools requires the contributions of all stakeholders, a key benefit of a contextually-relevant approach is the opportunity to recognize and develop the capacity of other teachers, leaders and community members to participate in and enhance continuous improvement efforts. When leaders engage in continuous improvement processes, they also increase their contextual literacy. Andreoli et al. (2019) reported that 10 school leaders in a three-year leadership development initiative who learned to lead change through action research interacted closely with other school members and shared ownership of the school improvement process. As a result, other members of the school community took on greater levels of leadership responsibility and began to approach school improvement processes with a deeper and more reflective and systematic perspective.

High needs school leader development

High needs schools require leaders who are able to identify and challenge the conditions limiting the success of their students while simultaneously meeting the demands placed on them by the increased accountability climate. Furthermore, these leaders need to be able to draw on a variety of strategies to develop the capacity of their schools to lead sustainable, systematic and systemic change. In this regard, leaders of high needs schools face additional challenges that require ongoing support (Duke, 2014; Lochmiller and Chesnut, 2016). In some high needs schools, such as ones in rural areas, these challenges can result in school leaders taking on a larger number of duties than leaders in schools without high needs (Hansen, 2018; Preston et al., 2013; Wieczorek and Manard, 2018). As a result of these additional burdens, leaders in high needs schools can have additional stress levels (Starr and White, 2008; Wood et al., 2013) and higher rates of turnover (Béteille et al., 2012).

Given the influence school leaders can have on students' academic outcomes (Day et al., 2016; Heck and Hallinger 2014; Louis et al., 2010), the detrimental effects of school leader turnover (Béteille et al., 2012) and the potential of professional development to enhance school leader retention (Goldring et al., 2014), there has been an increased focus on developing school leaders to address the challenges of improving the teaching and learning conditions in high needs schools (Herman et al., 2017; Manna, 2015). In the United States, this emphasis can be seen in ESSA (2015), which allows states the flexibility to direct their allocated funds to support leadership development efforts. In a review of states' ESSA accountability plans, which included the District of Columbia and Puerto Rico, Reedy and Doiron (2018) found that 44 of 52 plans described a focus on leadership development activities rather than simply enhancing compensation or advancement opportunities. This shift to structured leader development is noteworthy, since more focus has traditionally been centered on teacher development, and leadership development activities are rarely initiated by leaders themselves (Zepeda et al., 2014). Studies of successful districts in Canada (Leithwood and Azah, 2017) and the United States (Zepeda et al., 2014) have demonstrated that school leader professional development is a factor in school improvement success. Other studies have illustrated how large urban districts can provide collaborative professional learning experiences for school leaders focused on instruction (Louis et al., 2010; Honig, 2012; Honig and Rainey, 2014).

Leading high needs schools in contextually relevant ways that build capacity and enable continuous improvement efforts requires learning opportunities embedded in the context in which the leading and learning is to take place. This type of personalized learning opportunity can be provided through leadership coaching. Though coaching has been commonly used as a strategy for

supporting classroom teachers for many years, it is increasingly being used to support new and experienced school leaders (Louis et al., 2010; Reiss, 2015; Riley and Meredith, 2017).

As opposed to mentoring, coaching leaders involves those with expertise in school leadership working to develop leaders' knowledge and skills to address targeted areas for improvement (Goff et al., 2014; Grissom and Harrington, 2010). Though coaches may use a combination of blended strategies to assist leaders' development (Bloom et al., 2005; Reiss, 2015), the primary coaching approach is the use of questioning to engage leaders in critical self-reflection (Robertson, 2016). In this way, coaching is more personalized and effective than traditional one-size-fits-all forms of professional development (Lochmiller, 2014; Reiss, 2015).

Though leadership coaching typically occurs in the form of coach-leader pairings, the benefits of coaching can be enhanced when leaders are also able to participate in professional communities of their peers (Robertson, 2016). Like coaching, professional communities, have typically been seen as a vehicle for teacher development. However, they are more recently being considered valuable learning opportunities for school leaders. Professional communities are those in which participants have established norms of shared values, reflective dialog, de-privatized practice, a focus on student learning, and collaboration (Kruse et al., 1995). When school leaders participate in professional communities, they are able to learn with and from their colleagues and receive just-in-time advice from trusted peers.

While examples of leadership coaching and professional communities can be found in some larger, better resourced districts, smaller and less well-resourced districts often do not have the capacity to provide leaders with these forms of professional learning (Lock et al., 2012; Preston et al., 2013). The inability to provide their leaders with adequate professional learning opportunities to meet the challenges of their high needs schools has led to an increasing number of districts in the United States forming research practice partnerships with universities and other organizations (Coburn and Penuel, 2016; Coburn et al., 2013). Through research practice partnerships, schools are able to develop and implement research-based strategies to address their problems of practice while also serving as sites for furthering research on the topic.

Though still relatively limited in number, some districts have been able to form successful research practice partnerships to provide leadership coaching and professional communities for pre-service and in-service leaders of high needs schools (Cosner et al., 2018; Fusarelli et al., 2018; Klar and Huggins, 2020). In the case of Klar and Huggins (2020), faculty and graduate students from two universities and a consortium of 12 predominantly rural and high-poverty school districts formed a three-year research practice partnership called the Leadership Learning Community (LLC). Through the LLC, 10 school leaders (principals, assistant principals and teacher leaders) and eight leadership coaches (experienced principals and district leaders) attended monthly professional development sessions facilitated by the university-based faculty members. The content of the sessions related to leading collaborative and continuous change through action research cycles. In addition, the leadership coaches received professional development related to coaching strategies from the facilitators and met with their coaching peers in a professional community monthly (see Huggins et al., 2020).

The LLC leaders received coaching twice a month from their leadership coaches. These coaching sessions took place both in the leaders' schools and at off-site locations (see Andreoli et al., 2019; Klar et al., 2019a). Importantly, many of the leaders' districts did not have experienced school leaders who could serve as their leadership coaches. Instead, the leaders were paired with coaches from other districts. This aspect of the LLC highlights the challenges that some districts have supporting leadership development. Though it also created some logistical challenges for the coaches, leaders described a clear preference for having coaches from outside their districts who they could share their leadership challenges with in a non-evaluative environment.

As a result of participating in the LLC, leaders increased their abilities to lead change in their school, gained a greater understanding of how to engage other school-based members in improvement efforts and enabled distributed leadership practices that increased their schools' capacities to respond to their students' needs. The coaches also increased their understandings of how to use systemic and systematic change processes. Furthermore, they were able to use their newly developed coaching perspectives to work with other leaders in their own districts. In this way, this initiative's focus on leadership development and school improvement not only impacted the schools of leaders who participated in it but also other schools and districts in the consortium.

Though the LLC is merely one example of a research practice partnership, it illustrates the potential affordances of high needs districts seeking new forms of collaboration to address their leadership development challenges. It also adds to the growing research base on the role of school leader supervisors (Thessin, 2019). Importantly, the LLC demonstrated that leaders in high needs schools and districts can be supported in ways that increase their abilities to lead in contextually relevant ways that focus on building their school's capacities for leading systematic and sustainable change geared toward enhancing their teaching and learning environments.

Conclusion

Leaders of all schools have a moral obligation to meet the social, emotional and academic needs of their students in the process of preparing them for future success. Leaders of all schools must also meet the demands for accountability imposed on them by policy-makers and the general public. While all leaders may find achieving this balance of student interests and accountability demands challenging, leaders in high needs schools experience greater challenges in doing so than leaders in less challenging schools. Indeed, in the previous edition of this encyclopedia, Harris (2010) asked rhetorically whether improvement in such schools is even possible. Harris went on to say that, though challenging, both increased student outcomes and sustainable improvement are possible. Yet, to be successful "requires a school improvement process that fits the individual school context and is underpinned by an unrelenting focus on improving conditions at the learning level" (p. 781).

Ten years on, it remains the case that school leaders can successfully respond to the combination of student needs and accountability demands by engaging in contextually-relevant leadership practices, enhancing organizational learning through capacity building efforts and leading collaborative and continuous improvement processes that focus on enhancing teaching and learning practices within schools. However, leaders in high needs schools require additional levels of preparation and support to successfully meet the various challenges presented by their school contexts. In meeting these challenges school leaders benefit from personalized and job embedded learning opportunities geared toward addressing their own problems of practice, such as receiving leadership coaching and joining professional communities. To provide greater access to these types of professional learning in the United States, an increasing number of high needs school districts are forming research practice partnerships with universities and other organizations. Given the critical role the leaders of high needs school can play in enhancing the academic and career opportunities for the millions of children studying in them, it is essential that more research and funding be dedicated to this process.

Acknowledgment

I would like to thank Parker M. Andreoli for her valuable assistance in developing this manuscript.

Since at least the 1980s teacher leadership has been viewed as a panacea for many education ills. For decades, we have known that the two most significant school-level factor influencing student outcomes are teachers and school leaders (Chetty et al., 2011; Hanushek, 1992, 2010; Hanushek and Rivkin, 2012; Kane and Staiger, 2008; Leithwood et al., 2004; Rockoff, 2004). By combining “teacher” and “leadership,” policymakers, practitioners, and researchers hoped to identify an elegant solution to adaptive challenges related to unclear problems and solutions (Heifetz, 1994).

However, as is the case with most adaptive challenges, the solution has not been elegant or simple. Even the term, “teacher leadership” has remained somewhat ill-defined but widely used. Calls for teacher leadership increased (Curtis, 2013; Duncan, 2014; Pennington, 2013) and there were stronger arguments for why it was needed (Goldstein, 2014; Mangin and Stoelinga, 2008; Pounder, 2006). Advocacy for teacher leadership abounded. New models of and opportunities for teacher leadership proliferated (Alexandrou and Swaffield, 2014; Berry, 2010; Hargreaves and Fullan, 2012; Margolis, 2012). Substantial numbers of teachers have indicated they want opportunities to lead (MetLife, 2013).

Comprehensive reviews of the literature on teacher leadership have identified definitions, cultivated a theoretical grounding, advocated for enhanced teacher voice in policymaking, and indicated its role in school improvement with mostly distal connections to student outcomes (Murphy, 2005; Schott et al., 2020; Wenner and Campbell, 2017; York-Barr and Duke, 2004). Three literature reviews that examine teacher leadership literature from 1980 to 2018 and are particularly useful for framing the teacher leadership landscape (see Table 1).

Teacher leadership

York-Barr and Duke reviewed relevant literature from 1980 to 2002. According to their definition, teacher leadership is “the process by which teachers, individually or collectively, influence their colleagues, principals, and other members of school communities to improve teacher and learning practices with the aim of increased student learning and achievement” (2004, pp. 287–288). Others have attempted to expand this definition. For example, in the consultancy literature, Katzenmeyer and Moller (2009) broadened

Table 1 Teacher leadership literature since 1980.

	York-Barr and Duke (2004)	Wenner and Campbell (2017)	Schott et al. (2020) ^a
Years reviewed	1980–2002	2004–2013	2014–2018
Total studies included in review	34	83	84
Qualitative studies	19 (56%)	60 (74%)	59 (70%)
Quantitative studies	8 (23%)	3 (6%)	12 (14%)
Mixed methods studies	7 (21%)	20 (20%)	13 (16%)
Definition of teacher leadership	“The process by which teachers, individually or collectively, influence their colleagues, principals, and other members of school communities to improve teacher and learning practices with the aim of increased student learning and achievement” (p. 287–288).	“Teachers who maintain K-12 classroom-based teaching responsibilities, while also taking on leadership responsibilities outside of the classroom” (p. 5).	Authors recommend using York-Barr and Duke’s definition as they found that 39 (42%) of the studies included in their review lacked a definition of teacher leadership.

^aBased on analysis for Schott et al. (2020).

this definition, observing that “teacher leaders lead within and beyond the classroom; identify with and contribute to a community of teacher learners and leaders; influence others toward improved educational practice; and accept responsibility for achieving the outcomes of their leadership” (p. 6). York-Barr and Duke (2004) described a conceptual framework to guide inquiry into differentiated paths teachers take to organizational influence, professionalism, and teaching and learning. The framework has influenced subsequent teacher leadership research.

In their review of literature from 2004 to 2013, Wenner and Campbell (2017) found that teacher leadership research focused on roles beyond the classroom—roles that supported student outcomes by influencing policy outcomes and the professional learning of peers. Although the theoretical grounding improved since York-Barr and Duke’s review, the grounding remained limited and rarely focused on justice or equity issues. Wenner and Campbell highlighted the importance of administrators, school structures, and norms for supporting or constraining teacher leadership. Wenner and Campbell (2017) define teacher leadership as “teachers who maintain K-12 classroom-based teaching responsibilities, while also taking on leadership responsibilities outside of the classroom” (p. 5). The proliferation of various definitions or sometimes ill-defined teacher leadership has limited the theoretical grounding of the concept. However, their findings represented progress in relation to the grounding York-Barr and Duke described as “largely atheoretical” (2004, p. 291).

Schott et al. (2020) reviewed teacher leadership studies from 2014 to 2018. They recommended a return to York-Barr and Duke’s definition of teacher leadership to undergird the theoretical foundation of the research as 42% of the studies they included did not define teacher leadership. They also cited the methodological limitations of some of the studies and recommended greater attention to conceptual clarity, cross-country research designs, and attention to some of the negative aspects of teacher leadership as every study in their review demonstrated positive outcomes.

Teacher leadership development

There are several pathways by which teachers might come to leadership. Educational administrators may “appoint and anoint” teachers to leadership positions and leadership work outside the classroom (Smylie and Denny, 1990). Often, administrators are encouraged to share or “distribute” leadership work, involving teachers in decision-making and school improvement (e.g., Bryk et al., 2010; Louis et al., 2010; Spillane, 2006).

Another pathway to teacher leadership is initiated by teachers themselves. Teachers are encouraged to step forward and assume leadership at the school, district, and even state and federal policy levels. They are enticed with images of “superhero” teacher leaders and successful “teacherpreneurs” (Berry et al., 2013) and new influential roles at the national level (Eckert et al., 2016). They are exhorted to “speak truth to power” and to “bust” through the organizational, administrative, and institutions “cages” that constrain them (Hess, 2015).

While these paths can lead to productive leadership and some teachers may come to leadership by way of one or more of them, a more influential and sustainable pathway is teacher leadership development—the intentional, systematic, systemic development of teachers’ capacity for organizational-level leadership and its practice. The path of development is different from the paths of advocacy, exhortation, invitation, and self-initiation. None of those paths necessarily involve development and, indeed, few actually do. These other pathways become problematic as they assume that teachers who are tapped for or who self-initiate leadership possess the capacity and will receive adequate preparation and support to engage leadership work successfully. Advocacy for teacher leadership is not the same as the development of it. Building a new role or providing an opportunity for leadership does not mean that teachers will come forward or that they will be able to perform the work effectively (Smylie and Eckert, 2018).

Teacher leadership, even when well-supported, designed, and implemented is limited in its impact when performed in isolation from administrators. Therefore, educators, researchers, and policymakers have advocated for numerous forms of leadership – teacher (Murphy, 2005; Schott et al., 2020; Wenner and Campbell, 2017; York-Barr and Duke, 2004), distributed (Muijs and Harris, 2006; Spillane et al., 2001; Supovitz, 2008), transformational combined with instructional (Day et al., 2016) shared (MacBeath and Dempster, 2009), collaborative (DeWitt, 2017), or collective (Leithwood and Mascal, 2008; Louis et al., 2010). New models of leadership, particularly those involving teachers, have proliferated (Alexandrou and Swaffield, 2014; Berry et al., 2013; Hargreaves and Fullan, 2012; Margolis, 2012).

Teacher leadership through collective leadership

Regardless of the term or model used, education leadership requires teachers and administrators to work together toward shared organizational goals. Therefore, a more effective way to think about leadership for school improvement is to consider how to develop teachers and administrators together. “Collective leadership encompasses the practices through which teachers and administrators influence colleagues, policymakers, and others to improve teaching and learning” (Eckert, 2018, p. 5). Whether transformational, instructional, or both, collective leadership is a useful construct because it emphasizes joint goal setting and strategic implementation of those goals in the service of the primary purpose of schools – teaching and learning. This is an important stipulation because in some cases, terms such as distributed leadership have been reduced to task delegation from administrators to teachers. Moreover, collective leadership has been found to have greater influence on student outcomes than individual leadership (Louis et al., 2010). If this type of leadership can enhance collective teacher efficacy, the belief that faculty can positively affect

students, outcomes for students improve. Collective teacher efficacy is one of the most influential factors influencing student learning (Hattie, 2015).

Typically, schools and districts have focused on the practice of teacher and administrative leadership separately. This is inadequate for meaningful, sustainable school improvement that requires the coordinated leadership development of both teachers and administrators. There has been much less attention in scholarly and professional literature to teacher or administrator leadership development than to its purposes, design (e.g., attention to “hybrid” divisions of roles), its practice, and its efficacy. This lack of emphasis on development leads to practices in which teachers add work to the point of burnout or experience unhelpful delegation of work under the guise of leadership development (Eckert et al., 2016; Eckert, 2018). Emphasis on exceptional teachers simply doing more, delegating work differently, or focusing on individual leadership will do little to change complex education systems (Louis et al., 2010). Attention that has been paid to teacher leadership development has drawn primarily from the educational literature, notably research and writing from earlier efforts to implement teacher career ladders, master and mentor teacher programs, and participative decision making (Murphy, 2005; Schott et al., 2020; Wenner and Campbell, 2017; York-Barr and Duke, 2004).

Collective leadership development more accurately reflects the type of development necessary for school improvement as it addresses the mutual growth of teachers and administrators together (Eckert, 2019; Eckert and Butler, 2021). Literature on work design and redesign (e.g., Campion et al., 2005; Hackman and Oldham, 1980; Humphrey et al., 2007), leadership development generally and across organizational type and sector (e.g., Avolio, 2010; Conger, 1992; Day et al., 2004; Fulmer, 1997; Popper, 2005; Van Velsor et al., 2010; Yukl, 2013), and teacher leadership (e.g., Berg, 2018; Lieberman and Miller, 2004; Mangin and Stoelinga, 2008; Murphy, 2005; Wenner and Campbell, 2017; York-Barr and Duke, 2004) formed the foundation of a model of collective leadership development (see Fig. 1). Additionally, the early theoretical work design literature (Hackman and Oldham, 1980), form the conceptual foundation of collective leadership as a shift in the way teachers and administrators work and also has a way to examine collective leadership’s potential efficacy. The literature demonstrates two issues: there has not been enough focus on the “collective” or “development” of “collective leadership development.” Developing teacher and administrative leadership together have been overlooked in research and practice.

A model of collective leadership development

Fig. 1 represents a model of collective leadership development (Eckert and Butler, 2021).

The focus of the model is on leadership, not the leader, just as focusing on teaching instead of the teacher is beneficial (Hiebert and Stigler, 2017). This theory views leadership functionally (Firestone, 1996), as redesigned work to be performed rather than as a particular role to be assumed, considering this type of leadership as redesigned work (Mayrowetz et al., 2007; Smylie, 1994). The model captures the essential elements of a school, particularly as they relate to leadership for school improvement. The various elements influence leadership development. The theory supporting the analytic model posits that the development and performance of this new work is based on seven conditions:

- (1) A vision and strategy that is supported by dynamic, strategically “ambidextrous” leadership development (Fullan, 2005; Hargreaves and Fink, 2006; McCauley, 2008; Mumford et al., 2007; Mumford et al., 2007; Smylie, 2010; Tushman and O’Reilly, 1996) that is democratic, participative inclusive leadership (Bryk et al., 2010; Leithwood and Louis, 2012; Light, 1998);
- (2) Supportive administration that believes in this kind of leadership (Birky et al., 2006; Camburn et al., 2008; Murphy et al., 2009; Smylie and Brownlee-Conyers, 1992; Van Velsor et al., 2010) that recalibrates authority relationships (Murphy, 2005);
- (3) Resources and initial leadership capacity that provide the necessary talent, time, and space to lead together (Avolio and Hannah, 2008; Bond et al., 2008; Conger, 1992; Martineau, 2004);

Fig. 1 Collective leadership development model.

- (4) Adequate work design to facilitate collaboration, improvement, and the spread of teaching expertise (Campion et al., 2005; Hackman and Oldham, 1980; Margolis, 2012; Smylie and Denny, 1990);
- (5) Supportive social norms and working relationships that foster relational trust (Bryk and Schneider, 2002; Hargreaves and O'Connor, 2018; Muijs and Harris, 2007; Van Velsor and McCauley, 2004);
- (6) Shared influence of administrators and teachers on themselves and others (Day et al., 2004; Lai and Cheung, 2015; Muijs and Harris, 2007); and
- (7) Orientation toward improvement that facilitates growth (Eckert, 2018, 2019; Eckert and Daughtrey, 2019; Smylie and Eckert, 2018).

Of the seven conditions, the first four are antecedent to the other three, but there are systemic interactive relationships among all seven (Bass, 1990; Firestone, 1996; Smylie, 2010; Yukl, 2013).

Constructed primarily from the literature on teacher leadership and factors that influenced its practice (Murphy, 2005; York-Barr and Duke, 2004), the model builds on Wenner and Campbell's definition of teacher leadership in which teachers lead in and beyond the classroom (2017). The development experiences that flow from the seven conditions are not artificial team-building experiences. Instead, they are the work of school improvement that is co-led by teachers and administrators building on the notion that leadership is work to be performed rather than a particular role to be assumed (Firestone, 1996). The model frames collective leadership as work redesign, a case of broadening teachers' work from an exclusive focus on students and classroom instruction to working with colleagues, administrators, and policymakers at various levels. Work redesign through leadership development experiences is essential for both teachers and administrators if efforts are to be coordinated, sustained, and amplified. Leadership development through this shared work leads to increased relational trust (Bryk and Schneider, 2002; Tschannen-Moran, 2004) and professional capital—the systematic development of human, social, and decisional capital (Hargreaves and Fullan, 2012)—which leads to improved leadership development experiences, increased leadership capacity, and enhanced leadership practice and outcomes (Eckert and Butler, 2021). Effective practitioners of the leadership work in the service of shared goals becoming *de facto* leaders thus eliminating concerns about who should or should not be leading. The shared work identifies the leaders and flattens the organizational hierarchy (Skrtic, 1991).

In the model, dotted lines extend from the seven conditions beyond the development experiences as either supports or constraints to leadership capacity. For example, if a principal continues to expand the role of teachers based on their expertise and leadership in shared work, their collective leadership capacity will increase with the principal serving as a support. If, however, social norms and working relationships are poor, this condition will limit the teacher leaders' development of capacity. The model is iterative in that school leaders must attend to the seven conditions collectively and repeatedly to maximize growth. If any condition is under-developed, readiness for school improvement through collective leadership will be compromised.

As the collective leadership capacity of teachers and administrators increases, collective leadership practice should improve commensurately. As the model is predicated on work toward shared goals, leadership capacity and leadership practice are tightly-coupled. Improved leadership practice results in enhanced student outcomes. Because collective leadership is typically aligned with instructional practices, student learning gains, while still distal, are more proximal than other school improvement efforts such as facilities enhancement, resource allocation, or organizational re-structuring (Eckert, 2019).

Student learning outcomes in turn influence collective leadership practice, development experiences, and the seven conditions. The model results in a virtuous cycle of improvement as conditions improve even as external factors such as economic, social, and political realities influence school improvement. Due to the broad participation required by collective leadership, schools are more likely to find multiple, context-specific paths to improvement (Smylie and Eckert, 2018; Eckert, 2019). This concept of "equifinality" (Burke, 2014) is an important consideration when policymakers and educational leaders attempt to leverage collective leadership for school improvement. Collective leadership is not a formula or a top-down solution, but it can support continuous school improvement.

Teachers and administrators as catalysts for school improvement

Context matters a great deal in the development and enactment of leadership work. Principal support is a catalyst for leadership development and is contingent on initial teacher capacity, school conditions, resources, and work design. These antecedent factors shape the development experiences that either enhance or diminish trust in pursuit of improved collective leadership practice for improved student outcomes. A catalyst is something that accelerates a reaction. The catalyst is not the focus of the reaction. In an organizational context, a catalyst speeds up the work of others.

In schools where strong collective leadership exists, there is trust between school administrators and teachers that develops through catalytic relationships (Smylie et al., 2007). Principals are essential for instructional leadership development (Leithwood et al., 2004; Mangin, 2007) especially as it relates to shared vision and coherence (Firestone et al., 2005). Although teacher leadership is often used as an umbrella term for many school leadership efforts (Neumerski, 2012), collective leadership is even broader due to its inclusion of administrators.

Catalytic administrators serve particular roles in collective leadership development. They bridge and buffer external initiatives (Aldrich and Herker, 1977; Durand et al., 2015; DiPaola and Tschannen-Moran, 2005) as they bring coherence to school improvement by building connections to external groups and limiting work that does not serve teachers and students well. Their ability to

reduce the impact of outside demands on teachers increases the likelihood that collective leadership will lead to school improvement (Eckert, 2019). Because being a catalyst requires humility, the principals and their leadership teams are primarily composed of humble educators who are highly relational with other educators and students (Schein and Schein, 2018). Humble leaders express vulnerability and empathy for others and do not take credit for improving student outcomes. Instead, they highlight the work that others are doing (Eckert, 2018).

Principals' antecedent support of teacher leadership combined with the initial capacity of teachers for leadership is predictive of schools' opportunities for improvement. The impact of principal support is not related to the teacher to administrator ratio. In rural, urban, and suburban contexts with teacher to administrator ratios that ranged from 9:1 to 14:1, the development of collective leadership capacity through teacher-led initiatives, formal Professional Learning Communities, and informal problem-solving teams influences principal support and increased capacity of teachers in iterative feedback loops (Eckert, 2019). The capacity of the teachers for leadership work was central to the transformation of a school. Capacity can be constrained or supported by many factors such as preparation (Darling-Hammond et al., 2005; Jensen et al., 2016), professional development (Darling-Hammond et al., 2009; Jensen et al., 2016), or colleagues (Hattie, 2015; Jackson and Bruegmann, 2009; Ronfeldt et al., 2015). If teachers are already at capacity with their instructional responsibilities, adding additional work—even if it is meaningful—will not necessarily improve outcomes for students (Eckert et al., 2016).

Capacity is something that is malleable and can grow through deliberate practice. Deliberate practice is a vehicle for collective leadership development and is built into the analytic model. Deliberate practice is not just experience, it is practice that includes feedback, reflection, and opportunities for improvement (Ericsson et al., 1993). In schools, this occurs best with other educators. Over a ten-year period, teachers working in schools with strong professional environments improved 38% more than peers in schools with weak environments (Kraft and Papay, 2016). Additionally, student outcomes are dependent on collective teacher efficacy (Hattie, 2015). Where greater leadership capacity is perceived, a greater sense of teacher efficacy follows.

The establishment of relational trust (Bryk and Schneider, 2002) and the expansion of professional capital for teachers (Hargreaves and Fullan, 2012) is evident at schools with higher degrees of collective leadership. Teachers, administrators, and students collaboratively develop School Improvement Plans, teachers are leading staff meetings, and relationships between administrators, teachers, and school communities improve through shared work (Eckert, 2018). Leadership teams report that relational trust is essential for collective leadership development (Bryk and Schneider, 2002; Bryk et al., 2010). Unlike contractual trust—trust based on agreed upon conditions and work products—relational trust develops as teachers, students, and administrators respect others' work, value their competence, demonstrate integrity, and communicate personal regard for others (Bryk and Schneider, 2002). The ability to speak openly, honestly, and regularly is necessary between teachers and administrators. Often, effective communication manifests itself in administrators' "open door" policies for teachers who need to discuss issues or suggest opportunities for improvement. This openness is also needed for teachers to welcome others to observe their teaching. This openness is especially important in the development of followership (Day et al., 2004). Especially in contexts where collective leadership is being practiced, followership is not guaranteed, and therefore, the relationships developed through the work determine leaders and followers.

Another way to build relational trust is through the development of professional capital. Professional capital is comprised of human capital, social capital, and decisional capital. Improvement, both organizational and individual, occurs through transparent practice, collection of evidence and personal judgment, and collective responsibility coupled with collective accountability. The professional capital is most evident in schools that elevate leaders who were effective educators. Teachers or administrators who do effective work with students or colleagues in support of school improvement become leaders. Their credibility is derived from their expertise and rarely from their positions. This kind of professional capital is evident in schools with strong collective leadership, although the capital sometimes creates friction. With this kind of leadership rising from the student and classroom level, there are competing interests that require the support of teachers and administrators for support and coherence. Trust and professional capital are essential for accelerating collective leadership development and are often the result of effective development experiences and activities (Hargreaves and Fullan, 2012).

The future of teacher leadership for school improvement

While researchers and practitioners have made progress since the 1980s (Schott et al., 2020; Wenner and Campbell, 2017; York-Barr and Duke, 2004), much work remains for the development of teacher leadership as a vehicle for school improvement. Leadership work and development are done simultaneously and require both administrators and teachers. The design of the work (Hackman and Oldham, 1980), resources, and conditions influence the development experiences available to teachers and administrators. The work design of most schools can be challenging for collective leadership development. Providing time for collaboration, reciprocal observation, co-teaching, and planning varies depending on countries' education systems and other professions (Hiebert and Stigler, 2017; Jensen et al., 2014; Jensen et al., 2016; Margolis, 2012). Variation in work design exists across schools attempting to elevate the leadership of teachers. Depending on school size, there might not be formal roles for teacher leadership, opportunities for planning with other teachers in the same discipline, or job-embedded professional learning opportunities. However, even and especially in small schools, there is leadership work that needs to be done. The freedom that teachers derive from not being concerned with whom has a formal title to lead the work, allows them to step into the work and become *de facto* leaders. School climate can improve as a goal of the leadership work and also as a by-product of working alongside others. This improved climate leads to

more development experiences and meaningful changes in work design (Bryk et al., 2010; Eckert, 2019; Smylie, 2010). Further cross-country studies could inform ways to improve work design and leadership development.

One additional component of work design as it relates to collective leadership development is the sharing of evidence between schools for systemic improvement. Tony Bryk and his colleagues at the Carnegie Foundation (Bryk et al., 2015) prescribe networked improvement communities (NICs). They suggest systematically collecting evidence of what does and does not work and sharing those data between organizations committed to improvement. The impetus for data collection is not accountability, but improvement. Due to the need for reciprocal leadership development, this orientation toward improvement is about systematic development of which collective leadership must necessarily be a part. No longer do schools have a lone instructional leader. In a comprehensive high school with departments ranging from performing arts to English to world languages to science, the notion of one instructional leader is unrealistic. A school's orientation should be toward improvement, not overly simplistic accountability (Murphy, 2005; Smylie, 2010). This occurs through work that is done together by teachers and administrators. Leadership teams develop through mutual respect. To expand and scale this work, evidence of impact should be shared across schools, which requires work design that affords the time, opportunity, and networks for collective improvement around shared goals.

Introduction

School leaders are paramount in leading and sustaining school improvement efforts. In addition to managing day-to-day educational operations, school leaders represent their schools in their local communities, advocate for students, and supervise and support teachers. Most importantly, effective school leaders can support the creation of school environments that encourage excellent teaching, ensure consistent learning, and promote student engagement.

The importance of school principals is evident in the school reform and improvement literature. Drawing on research from 15 years of school improvement efforts in Chicago elementary schools, Bryk (2010) identified five “essential supports” for school improvement: (1) a coherent instruction guidance system, (2) professional capacity, (3) strong parent-community-school ties, (4) student-centered learning climate, and (5) leadership drives change. In addition to the key role that school leaders play in each of the first four essential supports, the fifth support exemplifies the central role of school principals in advancing instructional improvement efforts and uniting the entire school community around a common vision of improvement. Bryk (2010) argues that as they lead the process of school improvement, “principals cultivate a growing cadre of leaders (teachers, parents, and community members) who can help expand the reach of this work and share overall responsibility for improvement” (p. 25). In other words, school principals must simultaneously lead and cede, shouldering key responsibilities while surrendering some of their authority to other school stakeholders, especially teachers.

Although literature on “distributed leadership” illustrates the potential benefits of sharing leadership responsibilities among various school actors (e.g., Spillane, 2012), power sharing within schools also introduces the potential for conflict and misunderstanding about who should take on which roles. The sharing of responsibilities within schools also raises several important questions about school governance and leadership styles, such as whether the pie of school authority is fixed or capable of growing; who is better positioned to execute which roles; and how much supervision, support, or autonomy school principals should offer to teachers.

The importance of these questions has grown as many school systems across the globe decentralized in the 1990s and early 2000s, leading to an expansion of school autonomy and a greater role for school-level actors in school decision making (Jeong and Luschei, 2018). At the same time, some education systems (such as in the United States) have concentrated more educational decision making in the hands of the government, while other education systems have simultaneously devolved authority to schools while weakening decision making authority of teachers over their own instructional decisions (Jeong and Luschei, 2018). These diverging international trends illustrate the importance of considering the political and governance context to understand the manner and extent to which responsibilities are shared or contested within schools. For example, centralized education systems may concentrate decision making in supra-school entities like district or municipal offices, or even ministries of education. In contrast, decentralized systems are more likely to cede decision making to schools, in which case power may be concentrated in the hands of school principals or distributed across principals, teachers, or other actors. Yet since education systems generally do not vary within countries, it is difficult to examine the interaction between education system context and school-level decision making in a given country. As a result, an international comparative perspective is essential to understand how different configurations of school-level decision making relate to key outcomes like student achievement.

In this article, we apply an international comparative perspective to explore important questions about the role of principal and teacher authority in supporting school improvement and student achievement. By reviewing recent evidence—including our own published work—we aim to distill key lessons for how schools can organize and distribute authority appropriately and effectively across key school stakeholders, with a focus on school principals and teachers.

To explore the conceptual and empirical foundation for school-level power sharing, our conceptual framework lays out the competing perspectives of zero-sum versus variable-sum conceptions of school decision making authority. We then describe recent evidence regarding international trends in school governance and principal/teacher authority, distributed leadership, and ultimately, what the evidence tells us about how school governance may impact student achievement. We conclude with a set of concrete recommendations regarding the organization of school decision making and authority for school improvement.

Conceptual framework: a fixed or growing pie of power?

The question of whether and how authority is shared across school actors rests on competing ideas of power within schools as either fixed or variable. If power is fixed, then decision making authority cannot be allocated to one actor without being stripped from another. That is, power follows a “zero-sum” arrangement in which school principals cannot allocate authority to teachers without losing some of their own. By contrast, in variable-sum arrangements, school principals can cede decision making control without losing their own authority, resulting in a “win-win” relationship that increases the overall size of the “pie” of school-level power (Jeong and Luschei, 2018).

Power-sharing and trust in schools

Of course, the nature of power-sharing agreements undoubtedly varies across schools based on key conditions like principal leadership style and the capacity of school personnel. Perhaps most importantly, school leaders must trust their teachers to use their power to support the school’s vision of instructional improvement and raise student outcomes. Similarly, teachers must trust that principals will support their exercise of power and autonomy in the classroom and avoid undercutting new innovations and strategies.

Bryk (2010) describes the important role of school principals in establishing and nurturing trust in urban school communities, where power is often not shared across principals, teachers, and parents:

Principals establish both respect and personal regard when they acknowledge the vulnerabilities of others, actively listen to their concerns, and eschew arbitrary actions. If principals couple this empathy with a compelling school vision, and if teachers see their behavior as advancing this vision, their personal integrity is also affirmed. Then, assuming principals are competent at managing routine school affairs, an overall ethos conducive to building trust is likely to emerge (p. 27).

Leadership style and distributed leadership

In addition to competence, school principals’ leadership style will also influence how well they are able to engender trust among teachers to enable greater distribution of decision making authority across school actors. One key aspect of leadership style is whether school leaders ensure that their relationships with teachers are collaborative and supportive. A collaborative approach not only empowers teachers to take on greater decision making roles, but it can also promote greater effectiveness, creativity, and innovation on the part of teachers (Somech, 2010).

Collaborative leadership approaches can also lead to the sharing of responsibilities and roles through distributed approaches that empower teachers and other school actors to lead key aspects of school improvement (Spillane, 2012). From the perspective of the school leader, a central component of distributed leadership is their openness to sharing leadership functions with other school actors (Liu, 2020). Although distributed leadership implies the exercise of power by multiple actors, the approval and involvement of the school principal is an essential element in the presence and success of distributed leadership approaches (Printy and Liu, 2021). In other words, decision making authority cannot be shared across school actors if the school principal does not believe in or authorize collaborative approaches.

Empirical evidence

The positive potential of sharing decision making within schools is supported by a small but important set of empirical studies. In examining whether school power follows a zero- or variable-sum power-sharing arrangement, Shen and Xia’s (2012) analysis of the 1999–2000 Schools and Staffing Survey (SASS) found that principal and teacher authority are positively related across six of seven decision making dimensions, implying a variable-sum arrangement and an overall increase in school-level authority. However, Shen and Xia also found that such win-win relationships are more likely to occur at the elementary rather than secondary level. In a study of the 2004 SASS, Xia (2014) found positive relationships among principal and teacher decision making authority in five of seven decision making domains. Together, these results suggest that principal and teacher power sharing depends both on the context of the school and the decision making domain involved.

Context and decision making domain also appear to be important for the effectiveness of distributed leadership models, which by extending participation and decision making across multiple actors within a school site, assume the existence of variable-sum power-sharing arrangements. For example, [Printy and Liu's \(2021\)](#) analysis of data from the 2013 Teaching and Learning International Survey (TALIS) found that the distribution of school leadership is practiced and understood differently across countries. Printy and Liu also found that the relationship between principal and teacher leadership reports are positive and significant for some leadership functions, such as managing instruction, but negative for others, most notably organizational decision making. According to [Printy and Liu \(2021\)](#), these findings suggest that "principals think differently about who participates in leadership activity according to the situation." Specifically, whereas teachers are more likely to engage in activities and decisions related to instruction, teacher engagement is less likely in general organization decision making, where "principals most often retain hierarchical authority" (p. 316).

The need for an international perspective

Limited empirical evidence suggests that principals can share power with teachers without compromising their own decision making authority. One key avenue for doing so is the use of distributed leadership approaches that extend responsibilities and authority across many school actors. In fact, empirical evidence supports the exercise of distributed leadership for important school functions and outcomes. According to [Liu \(2020\)](#), distributed leadership is positively associated with school-level academic capacity, teachers' pedagogical skill and knowledge, teacher and principal motivation, perceptions of school cohesion, and teacher motivation. However, effective sharing or distribution of leadership responsibilities appears to be sensitive to the types and domains of decision making undertaken and the contexts under which leadership is practiced. Here the literature suggests the importance of cross-country differences, especially in terms of educational governance arrangements between governments and schools and within schools ([Printy and Liu, 2021](#)). In particular, the level of centralization or decentralization within an education system is likely to play an important role in how power is shared, and whether school principals act as agents of the government or as partners with teachers ([Jeong and Luschei, 2018](#)). Since educational governance generally varies little within a given country, a cross-country perspective is essential to understand relationships among educational governance, the sharing of authority within schools, and teachers' authority over their important classroom decisions. In the section that follows, we discuss evidence related to each of these importance pieces and how they relate to the central educational outcome of student achievement.

Principal and teacher decision making: who should do what?

International trends in school decision making

The 1990s and early 2000s brought a wave of educational decentralization across much of the globe, under the theory that local actors could solve educational problems more effectively than distant government bureaucrats. In many cases, this decentralizing trend brought new decision making authority to teachers, not just in the classroom, but also over issues such as school budgeting, staffing, and planning ([Eurydice, 2008](#)). This global trend was best exemplified by Finland, where teachers were empowered by a "culture of trust" to act as autonomous, well-trained professionals in their schools and classrooms ([Sahlberg, 2007](#)). Finland's stellar performance on the Program for International Student Assessment (PISA) and other international assessments provided evidence that investments in teacher preparation and autonomy represented a powerful way to raise student achievement. Finland's success was also cited to support growing calls for teacher professionalization, whose advocates argue that as well-trained professionals, teachers should be empowered to make key curricular and instructional decisions in their schools and classrooms ([Darling-Hammond, 2017](#); [Jeong and Luschei, 2018](#)).

Finland's performance notwithstanding, many other countries took a different approach toward school governance in the 1990s and 2000s, either centralizing overall school governance or decentralizing governance while concentrating school decision making in the hands of school principals and other non-teacher actors. In an analysis of educational decision making in 33 countries that participated in the 2000 and 2015 applications of PISA, [Jeong and Luschei \(2018\)](#) found that from 2000 to 2015, most of these countries actually centralized decision making in the hands of governments. Further, this centralization occurred not just in the domains of budgeting and staffing, but also in curriculum and instruction. In fact, 27 of 33 countries moved decision making authority over curriculum and instruction away from teachers and toward governments during this period. In contrast, school principals gained decision making authority over curriculum and instruction during the same period.

Surprisingly, [Jeong and Luschei \(2018\)](#) found that Finland, long identified with teacher professionalization and autonomy, was one of the 27 countries to centralize curricular and instructional decision making between 2000 and 2015. Not surprisingly, one of the countries with the largest moves toward centralization during this period was the United States. This period corresponded to the US No Child Left Behind (NCLB) reform, which increased the role of federal and state governments in standards-based accountability and oversight of school- and classroom-based decision making. Consequently, among the 33 countries in [Jeong and Luschei's \(2018\)](#) analysis, the United States was among the four countries with the highest level of overall centralization and was second only to Greece in terms of centralization of decisions related to curriculum and instruction.

[Jeong and Luschei's \(2018\)](#) study includes three important lessons for understanding the role of school decision making and the sharing of authority within schools:

1. Apparent global trends toward decentralization are actually much more nuanced than they appear, as decentralization can look very different within each country. For this reason, it is important to examine how decision making is shared *within schools*.
2. Despite global calls for teacher professionalization and autonomy, teachers in many countries have lost decision making authority over what happens in their own classrooms. This may be explained in part by the countervailing force of school accountability policies, best exemplified by NCLB in the United States.
3. Educational centralization and loss of decision making authority on the part of teachers does not imply a similar loss for school principals. In fact, during the same time that teachers lost decision making authority over curriculum and instruction, school principals gained authority in this domain.

School decision making and student achievement

Teachers' loss of authority over curriculum and instruction defies the logic that teachers know best how to address their students' needs and that they should have the autonomy to make key decisions regarding curriculum and instruction. In fact, research related to teacher autonomy indicates that teachers with greater autonomy have greater job satisfaction, motivation, and retention, which are all likely to be related to their effectiveness with students (Ingersoll, 2006; Ingersoll and May 2012; Jeong and Luschei, 2018). Consequently, the trends identified by Jeong and Luschei (2018) raise concern regarding the impact of teachers' loss of decision making authority on student achievement. More generally, the impact of teacher and principal authority on student achievement represents one of the most important illustrations of why policy makers and education officials should care about how decision making authority is shared within schools.

Although a fairly robust research literature has examined the impact of educational decentralization on student achievement, this research tends to look at school-level decision making as monolithic. That is, studies often examine the relative influence of government-versus school-level decision making across multiple dimensions or contexts on student achievement. For example, Fuchs and Woessmann (2007) found that greater school autonomy in the areas of textbook choice, hiring of teachers, and school budgeting is positively related to student achievement. Hanushek et al. (2013) found that decentralization has a more positive impact in more developed and higher capacity environments. However, this research does not examine how power is distributed across principals and teachers within schools. Yet as our conceptual framework emphasizes, power-sharing within schools can look very different across contexts, and such differences may be important to understand the impact of power sharing on student achievement.

In one of the few empirical studies to examine the relative importance of principal and teacher decision making authority for student achievement, Luschei and Jeong (2020) examined data from the 2015 PISA to assess whether perceived governance arrangements are related to students' PISA test scores. The authors found that increases in teacher decision making authority are consistently and positively related to student test scores in math, reading, and science. Further, this positive result tends to be greater in the domain of curriculum and instruction. In contrast to these positive results for teacher decision making, Luschei and Jeong (2020) found that decision making responsibilities of school principals are not significantly related to student achievement in any subject. When examining these relationships across different stakeholders and domains of decision making, the authors found that greater responsibility for school budgeting among school boards is consistently and positively related to student achievement in all subjects. However, greater decision making responsibility on the part of governments has a consistently negative or nonsignificant relationship with student achievement across all subject areas and decision making dimensions, suggesting a negative impact of educational centralization.

In addition to evidence supporting the positive benefits of sharing decision making authority with teachers, three other results from Luschei and Jeong's (2020) analysis deserve mention:

1. To examine the role of teacher capacity in decision making, the authors conducted additional analyses in which they categorized schools as high or low capacity according to the average level of teacher education in a school. They found that the positive relationship between teacher responsibilities and student achievement holds only in schools with high-capacity teachers. In schools with less educated teachers, the relationship between teacher responsibility and student achievement is not statistically significant. In other words, the positive results for teacher decision making appear to be largely driven by higher-capacity teachers. Additionally, the relationship between teacher decision making and student achievement is strongest for decision making related to curriculum and instruction. These results demonstrate once again that the impact of decentralizing school responsibilities or sharing power with teachers is not monolithic. Importantly, school leaders' decisions to share power with teachers must be informed by contextual considerations like the capacity of teachers and other school stakeholders, as higher-capacity schools are more likely to leverage greater autonomy to positively affect important outcomes like student achievement.
2. Luschei and Jeong (2020) also examined relationships among decision making authority and achievement across countries that were members of the OECD (representing wealthier countries) and those that were not OECD members. They found that the positive relationship between teacher decision making and student achievement is only significant in non-OECD countries. The impact of decision making by school boards also appears to be more positive in non-OECD countries. Although these results defy easy interpretation, they do suggest important cross-country differences in the impact of decision making arrangements. They also highlight a potentially important but understudied topic in educational governance, the role and impact of school boards on student achievement.

3. To understand the role of principals' leadership style, the authors also included models that controlled for various aspects of principal leadership style, as measured by PISA questionnaires that were filled out by school leaders. These variables include principals' responses related to (1) communication of school goals and curricular development, (2) instructional leadership, (3) promotion of instructional improvements and professional development, and (4) teacher participation in leadership. The analysis found only one of these variables to be significantly related to student achievement. This variable, which represents the degree to which principals are involved in teachers' classroom level decision making and problem solving, was negatively related to student achievement in all subjects. Additionally, the inclusion of principal leadership variables had little impact on the positive and significant relationship between teacher decision making and student achievement, which suggests that teacher decision making can have a positive impact on student learning regardless of principals' self-reported leadership style.

Conclusion and recommendations

Summary

In summarizing their review of literature related to the impact of school principals on students and schools, [Grissom et al. \(2021\)](#) observed, "it is difficult to envision an investment with a higher ceiling on its potential return than a successful effort to improve principal leadership" (p. 43). In this article, we argue that a key path to ensuring the effectiveness of principals is through the strategic sharing of decision making authority with teachers. We point to compelling evidence across education systems, subject matters, and domains of decision making that greater decision making responsibilities for teachers are consistently and positively related to student achievement. However, there are some caveats to this conclusion. First, we identified some evidence that the impact of sharing decision making with teachers varies according to national context, although this question needs further cross-national research. Second, the positive impact of teacher decision making is most apparent in the domain of curriculum and instruction, which is most directly aligned with the day-to-day "instructional core" of teachers' work. Finally, the positive impact of teacher decision making appears to be largely driven by more educated, or higher capacity, teachers. Consequently, principals must consider teacher capacity when deciding which responsibilities to devolve to whom.

Recommendations for organizing decision making for school improvement

Our review of conceptual and empirical literature leads us to make three tentative recommendations for organizing school-level decision making for school improvement.

1. Both school leaders and teachers must recognize that the sharing of decision making authority does not have to be a zero-sum game. The literature cited above offers evidence that decision making responsibilities for principals can grow along with those of teachers. The ample literature on distributed leadership also provides robust evidence for the positive potential of sharing leadership tasks within schools. However, the extent to which power can be shared appears to vary by context and according to decision making dimension, so principals and teachers must engage in power-sharing carefully, collaboratively, and with an eye toward how these arrangements may change as school contexts and conditions change.
2. To make collaborative decision making work, principals must build trust among teachers and other school stakeholders. School-level trust is the *sine qua non* of any collaborative school improvement effort. Teachers must trust that principals will recognize and support their professionalism, especially in the core areas of curriculum and instruction. Similarly, principals must trust that teachers will use their autonomy and authority to support a school-wide vision for improvement to make positive instructional changes for students.
3. Principals must share decision making authority strategically, considering both the type of decisions teachers are willing and able to make and the capacity of teachers to do so. Decisions related to curriculum and instruction are closest to teachers' training and day-to-day work, and they best encapsulate teachers' knowledge and skills as professionals. We have also presented evidence that among all decision making dimensions, teachers are most likely to use decisions related to curriculum and instruction to improve student achievement. On the other hand, inexperienced or less educated teachers may have less skill to leverage their authority or autonomy to improve instruction. In such cases, principals may need to supplement autonomy with support and professional development. As [Luschei and Jeong \(2020\)](#) argue, "The lesson for school leaders is to recognize which type of teaching staff they have and provide support or autonomy accordingly" (p. 363).

The ability to make constant improvements and adapt to a changing environment enables organizations not only to survive but also to increase their effectiveness over time (Collins, 2001; March, 1991). This focus on how organizations adapt to and work with their environments highlights the critical role that managing external demands plays in organizational development. From this perspective, the extent to which organizations are able to improve their performance depends on more than their internal characteristics; improvement depends on the relationship between the organization and the many other groups, organizations and institutions in the surrounding environment. By strategically managing their relationship with these other entities, organizations like schools can get access to information, resources and expertise and develop networks of connections that help them create coherent approaches to improvement that advance their organizational goals (Honig and Hatch, 2004). In this article, we describe one theoretical framework on capacity building in schools that helps to explain why managing demands is so important for organizational development; outline some key strategies education leaders can use to manage external demands; and provide a series of examples to explain the role that managing demands can play in school improvement efforts.

School capacity: what does it take to improve student learning?

Increasing access to and quality of schooling remains a central concern of societies around the world. In many cases, the hope is that enabling schools to be more effective will fuel a whole variety of benefits, including individual success, economic development, civic participation, and quality of life. Correspondingly, improvement efforts often focus on providing a series of “inputs” to schools – funding, curricula, qualified teachers – with the expectation that this infusion of resources will provide schools with the capacity to reach their goals. In a sense, this approach conceptualizes schools as containers that need to be filled: once schools have adequate resources, they should be able to reach their goals. This is a linear conception that underlies policy interventions like the development of Title 1 Elementary and Secondary Schools Act in 1965 and other “compensatory” programs in the United States around that time. These programs sought to achieve goals like improving schools and eliminating poverty by providing additional funds, curricula, or other programs to schools, particularly for schools in communities with lower levels of income and limited access to other resources.

By the 1980’s, however, the concerns about the continuing challenges of improving schools contributed to calls in the United States to rethink what it might take to improve schools and to go beyond providing more resources and to “restructure” schools entirely so that they could use those resources more effectively (Carnegie Forum on Education and the Economy, 1986; Elmore, 2004). At the same time, attention began to expand beyond schools themselves to consider the ways in which changes in many different aspects of education systems needed to be made (see for example, Smith and O’Day, 1990). The subsequent efforts to promote “systemic reform” in the United States also began to draw heavily on comparisons with countries that were seen as “higher-performing” on international tests like TIMMS and eventually the PISA tests that came into wider use in the 1990’s.

These shifts in some of the most prominent school improvement efforts at the time reflected a new and emerging view of school capacity that went beyond the typical focus on providing schools with additional resources (Cohen and Ball, 1999). First, this emerging view highlighted that simply having resources is not sufficient (Corcoran and Goertz, 1995; Malen and Rice, 2004). As Malen and Rice express it, a schools’ capacity to meet its goals depends on turning resources into expected outcomes (p. 636). In turn, education reformers began to highlight that maximizing the use of resources depends on the relationships among technical capital (funding, facilities, materials), the human capital (knowledge and expertise) needed to use those materials effectively, and social capital (networks of relationships and trust) that provides access to and facilitates the use of materials and the development of expertise (Cohen and Ball, 1999; Corcoran and Goertz, 1995; O’Day et al., 1995; Newmann et al., 2000; Putnam, 2000; Spillane et al., 2003; Spillane and Thompson, 1997).

Second, instead of treating schools as containers waiting to be filled, this view defined capacity as the “potential of material, a product person, or group, to fulfill a function if it is used in a particular way” (Newmann et al., 2000, p. 261). In this case, a school’s capacity to reach a particular goal depends both on the resources available and the complexity and magnitude of the work needed to accomplish that function (Hatch, 2001). For example, schools have low capacity if they have to get access to new materials, develop more expertise, or make substantial changes in their operations in order to enable all their students to reach high standards of achievement; but they have high capacity if few changes or additional investments are required to meet that goal. At the same time, the evaluations of the many standards-based and systemic reform efforts at the time, also highlighted changes in the structures, practices, and people in other aspects of the system that also needed to be made in order for schools to develop the capacity to meet these ambitious goals (Goertz et al., 1996; Fullan, 1999; O’Day and Smith, 1993).

An analogy to the evolution of municipal water systems helps to illustrate this new relational view of capacity (Hatch, 2009). In the early 1900’s urban centers needed a much larger supply of water. Initially, efforts focused on increasing the supply of water – by building more and bigger dams and reservoirs and expanding the amount of water they could deliver. The economic and ecological costs, however, quickly demonstrated the limits of that approach. Consequently, municipalities began to turn their attention to managing the *demand* for water: developing appliances that used less water and educating the public about the benefits of conserving water. Controlling demand lessened the pressures to increase the supply.

This analogy reveals that the capacity to meet particular goals – whether to provide 24/7 access to water or to increase student learning outcomes – is a function of the resources available and the demands that exist. Thus, increasing supply and the amount of resources available is only one means of building capacity. Monitoring and managing the demands on the system plays a critical role in building capacity as well. Returning to the analogy also illustrates that the extent to which the resources available meet the current demands for water can also be affected by a host of contextual factors including weather patterns, technological developments, and demographic changes. Furthermore, managing the water supply not only involves factoring in the external conditions, it also requires acting systematically – considering the connections among different neighborhoods and different regions and the way their interactions affect supply and demand.

In terms of schools, several lessons stand out. First, building the capacity to improve student learning depends on the relationship between the school and the surrounding community: changing the demands placed on schools can change the resources and the amount of effort schools need to achieve their goals. Second, schools face all kinds of demands that they do not always have the capacity to meet (Hatch, 2002). These include demands to meet performance goals on conventional measures such as attendance, test scores, and graduation rates. However, schools are also expected to fulfill a variety of other implicit and explicit functions such as housing and looking after school-age children for a good portion of the work day. Schools also face a wide variety of demands for compliance and conformity from the district, the state, support providers, students, families and others who expect them to implement certain practices and operate in certain ways. In particular, all schools – and in fact all educational entities – have to contend with the general expectations about what “real school” and “real learning” look like (Hatch, 2021; Metz, 1988; Tyack and Cuban, 1995). As a consequence, schools face multiple, often conflicting demands that can sap time and energy and may undermine rather than enhance their ability to achieve their performance goals.

Strategically managing external demands

Despite the challenges, schools can strategically manage external demands. In a review of literature related to policy coherence and organizational learning, Honig and Hatch (2004) identify a number of approaches schools can utilize to recognize and deal with external demands. First, goal setting creates a framework that can help members of an organization to understand what they are supposed to do and to identify external resources and opportunities that can help them meet those goals. This framework serves as a “simplification system” that enables organization members to make sense of complex and conflicting information and to make complex problems manageable (March, 1994; Weick, 1995). Without some common understanding of their purposes and goals, organization members have little direction to help them make decisions or to decide what aspects of the external environment to pay attention to. In particular, educators benefit from having a shared understanding of goals that are both specific and open-ended: providing some direction but also allowing for diverse views and the development of new information and expertise that can lead to productive adaptations.

Second, organizations can take advantage of two general approaches to help them manage external demands and use them to advance their collective goals: bridging and buffering. Bridging involves engaging with external demands in order to gain information, resources, and assistance. Bridging strategies include “pulling the environment in” by working with and incorporating people and groups in their external environment into their own activities. These efforts blur the boundaries between the organization and the external environment, fostering the development of reciprocal relationships, facilitating the sharing of information, expertise, and resources, and supporting mutual adaptation. Developing these relationships also gives organizations opportunities to “shape the terms of compliance” by influencing the demands that they have to face. For example, organizations that develop connections to policymakers by including them on their boards and among their advisors can both gain information about policies in development and can provide information and advocacy that encourages policymakers to develop initiatives that reflect the organization’s goals and interests.

Conversely, buffering involves deliberate efforts to deflect or ignore external demands. Buffering strategies include attempting to “suspend ties to the environment” as much as possible. For example, schools may choose to apply for magnet or charter status or to operate as private schools in order to avoid having to respond to the demands of the public education system. Public schools may

also choose to avoid some external demands by seeking waivers that allow them to avoid demands (such as those associated with particular evaluation systems), choosing not participate in particular programs or refusing funds that bring additional demands. Notably, however, it is extremely difficult for schools to be able to eliminate all external demands. Even schools that operate outside the regulations of public education systems still have to contend with the expectations and requirements of students, parents, and other institutions with whom they interact.

Despite their differences, bridging and buffering are not mutually exclusive strategies. Organizations can use strategies that reflect both approaches at the same time – connecting to some external groups and some demands while attempting to ignore or protect themselves from others. Several strategies reflect a “hybrid” approach that involves both bridging and buffering simultaneously. For example, developing “peripheral structures” enables organizations to deal with some external demands while insulating other units and members of the organization from those demands (Elmore and McLaughlin, 1988) (in other words, partially suspending ties with their environment). Organizations can also symbolically respond to or adopt external demands (Cuban, 1984; DiMaggio and Powell, 1983; Meyer and Rowan, 1977; Zajac and Westphal, 1994). For example, a school might develop a strategic plan that incorporates goals and activities required by external authorities, but then may not implement that plan; or organizations may adopt language, terms and structures that make it sound and look like the organization is responding, without actually altering any of their core operations.

The literature on how organizations deal with external demands suggests several key lessons for education leaders. First, members of organizations respond to their environment by bridging and buffering all the time. However, educators are better able to strategically manage those demands when members of the organization have a shared understanding of their goals and work collectively to use bridging and buffering strategies explicitly to advance their goals. Second, members of organizations, the units within them, and the other organizations they are connected to, are also all attempting to manage external demands at the same time. Therefore, members of other organizations like staff of district and municipal offices, external support providers, and state agencies can help schools to manage external demands or they can contribute to the demands to which schools have to respond (or both). As a consequence, developing and maintaining relationships with key actors in the external environment remains a crucial ingredient for managing external demands. In addition, deliberate efforts by education leaders, policy makers, and funders to support common goals, shared understanding, coordinated activity, and collective impact across organizations can create an environment that makes managing external demands easier rather than harder (Kania and Kramer, 2011).

Illustrations: managing external demands in schools, networks, and systems

In the sections that follow, we review research on how members of organizations manage external demands at the level of the school, system, and network and the lessons for education.

Managing external demands in schools: integration or adoption?

In practice, capable school leaders are able to bridge to and integrate external demands in ways that reinforce and advance internal priorities. In the process, they help to craft a shared coherent, understanding of what school members are supposed to do when faced with different choices and conflicting demands (Honig and Hatch, 2004). By contrast, schools with weaker leaders are more likely to accept and adopt the goals of external policies as their internal priorities (Louis and Robinson, 2012). In the process, schools become focused on implementing the initiatives developed by others; and their members have to figure out how to deal with the competing expectations largely on their own. Given the number and short shelf life of many improvement policies and initiatives, adopting the goals of external initiatives opens schools up to considerable uncertainty and leaves them vulnerable to the constant changes in their environment.

Integrating external demands rather than adopting them wholesale depends on leaders who can foster a shared understanding of school priorities (Fullan and Quinn, 2015; Johnson et al., 2014) and can establish what Abelman et al. (1999) describe as “internal accountability” or what Forman et al. (2017) describe as a school’s level of “internal coherence,” or “the collective capability ... to connect and align resources to carry out an improvement strategy” (p. 2–3). Internal accountability and coherence develop as leaders put in place structures and processes that support the development of relationships, sharing of information and expertise, and a sense of collective responsibility (Hatch, 2020). This internal coherence then serves as a foundation for distributed leadership (Harris and Spillane, 2008) and enables many members of the school to advance the school’s interests. The effective integration of external demands is also more likely when schools have more capable instructional leaders – principals and teachers who are knowledgeable about standards, subject matter, and the leadership practices that can improve teaching and learning (Kaufman and Berglund, 2018; Stein and Nelson, 2003) – and have stronger organizational structures and resources for professional learning.

In addition to focusing on developing the structures and processes inside their schools, school leaders can manage external demands by drawing on several different strategies for working with people and groups outside their organization (Hatch, 2009). In particular, leaders can cultivate connections with key allies and share information with them about their school’s goals, needs, and operations. These connections enable leaders to “scan the environment” (Honig and Hatch, 2004) by giving them access to information about what’s happening in other organizations and what may happen in the future. This information can help leaders to anticipate changes in external demands and conditions and to prepare to respond. At the same time, these connections

enable leaders to “seed” the environment by giving them allies in the external environment who can help to develop new policies and initiatives that already reflect the needs and concerns of the school. In addition, these connections give schools access to people who can advocate on the schools’ behalf to help shape the terms of compliance and to help schools get waivers or other means of buffering from problematic demands.

In a study of the implementation of new academic standards for students and a new teacher evaluation policy in three high-poverty elementary schools in New York, for example, one principal leveraged these policies to strengthen existing curriculum and better address the needs of their students, particularly English learners (Stosich, 2018). Teachers in this school described engaging in professional development and receiving instructional feedback that supported them in learning how to use and adapt their existing curriculum to meet the new standards, the expectations for teacher evaluation, and their students’ needs. Furthermore, the school’s sustained work with a curriculum developer provided access to new materials and support for professional learning as they navigated the shifts required by the new standards while building on their ongoing efforts to strengthen instruction in English language arts.

By contrast, the other two schools in the study lacked a well-defined vision for curriculum and instruction. Notably, one school lacked a well-defined curriculum and the curriculum had changed frequently in the other school, leaving teachers in both schools without sustained opportunities for learning how to use curriculum to implement the new academic standards. In these instances, the principals adopted the practices described in the teacher evaluation framework as their school priorities. Given the limited attention to curriculum, educators in both schools focused on the pedagogical approaches outlined in the teacher evaluation framework as a way of simplifying the work of teaching to the new standards; however, this strategy failed to bring attention to how these instructional strategies would be used to address specific content and students’ learning needs. Teacher evaluation policies focus on teachers’ pedagogy, whereas academic standards focus on students’ learning; thus, responding to the demands of more student-focused policies may present a greater challenge for educators than teacher-focused policies. For these schools, the implementation of the teacher evaluation framework detracted attention from the new standards for students in the two schools with lower levels of organizational capacity.

Leveraging networks to sustain attention to internal goals in the face of external change

Beyond independent connections with different individuals and groups, school leaders can also form or join networks of organizations that share some goals and interests. Like schools, networks with shared goals and a history of success may be better able to buffer themselves from problematic policies and initiatives while maintaining their legitimacy. Research on the Internationals Network for Public Schools in the United States presents one promising example (Jaffe-Walter, 2008). The network of high schools serves newcomer youth who have been in the country for four years or less at their time of admission and are learning English and is organized based on common principles that prioritize project-based learning and collaborative inquiry for students and educators.

Since the network was founded in the 1990s, increased focus on standardization and high-stakes testing has presented a challenge for the network and member schools as they work to maintain their focus on interdisciplinary, project-based learning in the face of narrower, content-based external assessments. As Jaffe-Walter (2008) explains, “the network is critical because it provides a space for educators to explore ways of implementing core commitments in the context of external pressures” (p. 2053). This research suggests that the network is not only a place for collectively negotiating how to respond to conflicting demands while maintaining core commitments but can also be a site for reactivating a collective memory of resistance to inform responses to new demands. Notably, this network is strongly positioned to buffer external policies given the success of network schools in supporting recent immigrants and English learners in graduating from high school at much higher rates than other schools in their same school districts. Even in successful networks, however, negotiating the connections between external demands and internal priorities is an ongoing process. Thus, as policies increased the number of both formative and summative assessments required for high school graduation, educators in the study described an ongoing debate with colleagues in their school and across schools in the network about the extent to which they should allow external assessment policies to influence internal priorities. Networks can connect schools with the technical, human, and social capital that increases capacity for sustaining attention to internal goals even in the face of competing or conflicting external demands.

Creating a context for coherence: managing external demands at the system level

Reflecting the relationship between schools and the context with which they interact, school leaders’ ability to manage external demands depends as well on the extent to which district administrations, external support providers, and other organizations and government agencies contribute to or mitigate multiple, conflicting demands. Notably, district administrators can amplify conflicting demands if they respond to new policies and initiatives by adding layers of requirements to facilitate monitoring and to ensure compliance at the school level. Such amplification becomes even more problematic when municipalities and national governments create several new policies at once or when those policies are in conflict with others that are already in place. For example, in the US, the adoptions by many states of the Common Core Learning Standards and new teacher evaluation approaches required by the Federal Race to the Top legislation created separate demands for professional development and training that schools and districts had to figure out how to coordinate (Stosich et al., 2021).

Relatedly, policymakers can make it more difficult for schools to implement policies if they fail to acknowledge the need to build new capabilities to meet the new demands. According to [Elmore's \(2004\)](#) theory of reciprocal accountability: "If the formal authority of my role requires that I hold you accountable for some action or outcome, then I have an equal and complementary responsibility to ensure you have the capacity to do what I am asking you to do" (p. 68). In practice, however, schools and districts often complain that new policies include "unfunded" mandates and related demands that schools have not been given the funds and means to meet.

At the same time, district administrators and municipal and national policymakers can also work to align external demands and act in ways that help schools to coordinate those demands effectively. Alignment describes the process of lining up policy expectations, resources, and rewards or consequences so that they create a consistent and linked set of demands. In Singapore, for example, regular, systematic reviews of curriculum in each subject are centrally coordinated with work on professional development and assessment. In the US, the "systemic" reforms of the 1990's also sought explicitly to encourage states to develop higher standards for student learning and to align the development of assessments, teacher preparation, and other supports with those new standards.

Nonetheless, alignment is not the same thing as coherence, and even highly coordinated reforms can be experienced as incoherent and overwhelming if educators do not have sufficient support. Coherence is a "state of mind" that can result from educators' experience with external demands and the degree to which they interpret them as connected and reinforcing shared goals ([Hatch, 2015](#), p. 105). Thus, coherence is not a characteristic of these demands but rather a perception that is developed and renegotiated over time as educators are confronted with new information and experiences.

Intentional efforts from district leaders to bring together educators to make sense of and learn about new initiatives can contribute to the development of the close social ties necessary for sharing complex information and encouraging a sense of coherence and coordination ([Hodge and Stosich, 2022](#); [Stosich et al., 2021](#)). District leaders can use organizing routines, such as creating opportunities for shared observation of instructional practice or learning about shared tools, to encourage coordination across individuals and roles ([Hatch et al., 2016](#)). Coordination of activities around shared goals has been identified as a key attribute of effective organizations, both inside and outside of education ([Lawler, 1990](#); [Stosich, 2017](#); [Wohlstetter et al., 1994](#)).

In addition, the nature of particular policies may encourage coordination among actors in the same roles, across roles, or present unique challenges for coordination. For instance, studying the efforts of school and district leaders to implement common academic standards for students and a new teacher evaluation framework, we found that the teacher evaluation framework, which focused on aspects of teaching that were presumed to apply across levels and disciplines, allowed for shared learning experiences for educational leaders across roles. By contrast, the districts focused opportunities for learning about academic standards on teachers rather than school leaders, and these opportunities were organized based on content area and grade-level, limiting opportunities for teachers and leaders across roles to develop common understandings and approaches to support implementation of the new expectations for students. Thus, the design of academic standards presented a unique challenge for coordinating the work of administrators as reform leaders ([Stosich, 2018](#); [Stosich et al., 2021](#)).

Municipalities and national systems can also support coherence by putting in place mechanisms that bring together stakeholders to develop common understanding of educational goals and to foster the collective responsibility to meet them. For example, roughly every ten years Finland has engaged in a curriculum renewal process which supports collective reflections on the goals of the comprehensive education system since it was established in the 1970s ([Hatch et al., 2021](#)). The process has evolved over time, but in the last two renewal cycles there has been extensive involvement of key education stakeholders from the very beginning of the discussions. Numerous "curriculum groups" go to work developing the guidelines and objectives in each subject and aspect of the core curriculum. Teachers are at the center of these committees, though the committees also include school leaders, municipal administrators, teacher educators, and researchers among others (and many of those other representatives have themselves been teachers at some point in time). In addition, an advisory board overseeing the whole process includes a cross-section of representatives of teachers, school leaders, parents, students, textbook publishers, researchers, teacher educators, ethnic groups (for instance representatives of the Sami people), and municipalities. Recommendations for changes in the curriculum framework are then discussed and debated by committees of stakeholders at both the municipal and local school levels. The wide engagement of teachers, leaders, teacher educators, textbook publishers, researchers, parents, students and others in the process creates connections among stakeholders at different levels of the system. In turn, those "bridges" give those at the school level the opportunity to influence policy development at both the municipal and national levels and those at the local level also get information and knowledge about major changes *long before those changes are actually made*. As a consequence, schools all across the country are more likely to be ready to head in new directions in concert. More than a mere adjustment to ensure the system is "aligned", however, the curriculum renewal process can also be seen as an opportunity for many people to develop a sense of coherence and an understanding of why schools are doing what they are being asked to do.

Summary

The research on the role of external demands in organizational development shows that leaders have to look beyond the boundaries of their own authority. Effective governance and leadership depend on the abilities to work with and influence those individuals and groups who are both inside and outside schools and districts. In particular, to manage external demands, leaders have to make choices about when to bridge and buffer – when to engage with and when to protect their organizations from external forces.

At the same time, leaders have to learn how to balance their time and energy – focusing enough attention on understanding and dealing with external forces while still attending to and supporting those who report to them directly. To achieve that balance, leaders can foster shared understanding and common priorities with both internal colleagues and external allies, enabling both to advance their collective interests.

When considering which strategies might best achieve their desired goals, leaders of schools, networks, district offices, states and other organizations can also consider their context, including the historical investment in internal priorities, the current capacity of educators to achieve these goals, and the extent to which the policy environment is supportive. Sustained investment, high levels of educator capacity, and strong social networks that reinforce shared goals can support schools in advancing internal priorities while effectively managing external demands. Notably, at each level of the system educational leaders not only manage demands but also create them. The introduction of additional policies or programs, even when complementary, increases the complexity of policy implementation and, thus, may require increased and coordinated leadership support for successful integration in practice.

Introduction

Over the past 30 years, schools have had to be responsive to different fragmented educational policies aimed at improving teaching and learning, including standard-based reforms, the increased demand for accountability, and the growing marketization in education. In addition to these pressures to coordinate the pursuit of excellence and equity from system actors (e.g. state agencies, district offices, school administration), different so-called non-system actors (e.g. voluntary and professional organizations, universities, and private firms) have taken a stronger role in the governance of education, the provision of educational services and the implementation of policy. These changes have altered the institutional landscape of schools worldwide (Cohen et al., 2018). Schools also have faced broader social environmental changes such as shifts in student demographics, increased teacher shortages, the call for customization, the growing social inequality in education, and more recently the rise and rapidly spreading of the COVID-19 pandemic. To effectively cope with these changes, schools have to develop their school-wide capacity to improve teaching and student learning. As a consequence, building the improvement capacity of schools has become a key challenge for practitioners, policymakers and educational researchers.

In their efforts to understand the nature and dynamics of school improvement as an organizational process, the vast majority of scholars conducted qualitative case studies and large-scale quantitative cross-sectional surveys. These studies have offered a “one-time snapshot” of leadership practices and school conditions that support teaching and learning (e.g. Hallinger and Heck, 1998; Slegers et al., 2002). More recently, scholars have begun to use longitudinal research designs to investigate the process of building school-wide capacity for improvement over time and patterns of change during schools’ improvement journeys (e.g. Duff, 2021; Hallinger and Heck, 2011; Heck and Hallinger, 2009, 2010a,b; Mulford and Silins, 2011; Thoonen et al., 2012; Slegers et al., 2014). Although substantial progress has been made, school improvement research faces some conceptual and methodological challenges (Feldhof and Radisch, 2021). The goal of this chapter is to summarize the key findings of school improvement research and discuss one of the key conceptual challenges facing school improvement research. I do so by arguing for using a systemic perspective to better understand the complexity and dynamics of school improvement as a system wide phenomenon.

The structure of the chapter mirrors this goal. I will start by discussing the different perspectives scholars have used in analyzing supportive conditions and processes associated with school improvement. I then sketch the key findings of the large body of school improvement research, making a distinction between studies using case study and cross-sectional designs on the one hand and longitudinal designs on the other. Following this overview, I elaborate on the potential of using a systemic perspective to investigate

how schools, that are embedded in a broader educational system, can build school capacity for improvement. I end the chapter with some suggestions for future research.

Perspectives on school improvement

In conceptualizing school improvement scholars have used a variety of theoretical perspectives (Slegers and Leitwood, 2010). Below, I briefly discuss these perspectives that are often grounded in different assumptions and research traditions.

Planned change

Since the late 1970s, scholars have started to frame school improvement as a form of planned change, while taking the school as the key unit of change. An important perspective on the process of implementing change in schools has been the modeling of school improvement as overlapping developmental stages, including adaptation, implementation and institutionalization (Fullan, 1991). This line of inquiry focused on processes of personal change (Evans, 1996; Rogers, 2003), organizational change (O'Toole, 1995) and educational change (Hall and Hord, 2006; Van den Berg and Slegers, 1996a,b), identifying the impact of mechanism, strategies and "change agents" at various stages in the change process. Findings from these studies indicate that reform programs have been often changed during implementation through "mutual adaptation" and that events and structures limit the impact of managing change successfully (Berman and McLaughlin, 1978; Firestone and Corbett, 1988; Louis and Miles, 1990; Van den Berg and Slegers, 1996a).

Policy implementation

Researchers studying the implementation of standards-based and accountability reforms reframed the notion of mutual adaption as a learning process and a lack of alignment between local, district and state policies as key mechanisms by which policy influences school and class instructional practice (Coburn et al., 2016). This research has demonstrated how educators (administrators, school leaders and teachers) respond to policy reforms and that their understanding of policy is shaped by their own beliefs about "good" instruction. This often resulted in the reinforcing of preexisting practices, the transformation of innovative curricula into traditional ones and the adoption of surface-level changes rather than deeper fundamental changes to instructional practice. Research in this domain has also identified that system leaders' sense making, organizational routines and artifacts in schools play an important role in how the work of organizing for, and supporting instruction is coupled with the broader institutional environment (Spillane and Burch, 2006; Spillane et al., 2011, 2019; Woulfin, 2015).

Effective schools

A great deal of evidence for school-wide interventions to improve teaching and student learning has emerged from the knowledge base on effective teaching and schools. This line of research has focused on "what works" to guarantee school success, leading to a variety of lists of educational effectiveness enhancing conditions (see for example Scheerens, 2016). Although many of the variables included are amenable to school-wide interventions, the issue of how to build school-wide capacity for less effective schools to become more effective has not been addressed (Louis et al., 1999; Duff, 2021). Scholars have, therefore, called for a synthesis of school effectiveness with school improvement research (Reynolds et al., 2000; Slegers et al., 2002). Comprehensive School Reform Programs can be seen as reform designs or models that are grounded in educational effectiveness research and offer solutions to schools' improvement problems. Research into the effects and implementation of these models have found modest to positive effects on student achievement scores examined (Borman et al., 2003). Moreover, most of the models were actively shaped and reshaped ("co-constructed") by teachers, school leaders and other local educators to accommodate the various aspects of the models to the local context, thereby underlining the important role "mutual adaptation" plays in implementing reform programs as founded in earlier research (Datnow et al., 2002).

School culture

Another perspective emerged from research that focused on how school culture shapes educational reforms and connects to school improvement (Rosenholtz, 1991; Sarason, 1982). Researchers have highlighted the importance of a strong school culture as the softer strategy in school improvement and believed that "reculturing" is crucial to entail deep change (Fullan, 2000). In exploring the link between school culture and school improvement, scholars have situated professional learning communities and organizational learning as the building blocks for school culture (Leithwood and Louis, 1998; Louis et al., 1996; Mitchell and Sackney, 2000; Lee and Louis, 2019). This work suggests that teachers' collaborations as organizational mechanism provide the habits of searching for ideas, sharing information with colleagues and of generating new ideas within and from outside the school. Findings have shown that dimensions of organizational learning and PLC promote teaching and learning (Bolam et al., 2005; Lomos et al., 2011; Vescio et al., 2008).

Social networks

More recently, scholars have started to investigate how social relations between teachers may support school improvement, using social network theory (Daly, 2010). The study of social networks in schools have granted more attention to the social embeddedness of teachers' social relationships in the informal patterns of interaction in schools that play a role in the exchange of knowledge, information and materials, and the facilitation of individual and collective action. This research views the school as an organization from a social interactional perspective in which teachers' interactions are assumed to create opportunities for professional learning in support of school-wide capacity for improvement (Sleegers et al., 2018). The concepts and tools offered by social network theory and research supply opportunities for understanding more fully the conditions, processes and outcomes of school improvement and educational change.

School improvement journeys

As school leaders must take the environmental and organizational conditions into account as they work toward continuous school improvement, researchers have started to investigate the relationship between schools' contexts, leadership practices, and improvement processes during change (Day et al., 2011; Duff, 2021; Hallinger and Heck, 2011). They try to analyze different patterns or stages in the journey of school improvement and relate these patterns to contextual conditions. Findings from the few studies conducted so far have started to increase our knowledge of how building school-wide capacity is embedded in the school improvement context.

Inside and outside views

Sleegers and Leithwood (2010) identified two views that underlie the different perspectives that dominated research on school improvement and educational change. The first view, which they term the "inside" view, focuses on the capacity of schools to transform themselves into supportive environments for teacher and student learning. By focusing on the professional growth of teachers and the problem-solving capacities of the system itself, change is considered as part of a larger process of making sense of situations through individual and collective learning. The second view, the "outside" view, concerns the implementation of policy reforms into schools to improve the quality of instruction and enhance student learning. This view focuses on the attempts of reform policies and those who are charged with their implementation to force or induce changes in teachers' practice via mandates, incentives and normative pressures. Although these two views use different assumptions about the nature and direction of school improvement and educational change, they inform each other. According to Sleegers and Leithwood (2010), findings from school improvement research suggest that schools with high improvement capacity are not only better able to transform themselves into supportive contexts for teaching and learning but also to effectively respond to the pressures of external change and align the various goals, materials and demands of policy programs to the local context. So, school capacity for improvement connects research on top-down (external view) and bottom-up approaches (internal view) to school improvement and is considered an important prerequisite for continuous and sustained school improvement (Sleegers et al., 2014).

In the next sections, I therefore will look at research on school improvement through the lens of school capacity for improvement and will organize a wide range of studies that have provided insights into conditions that foster continuous school improvement. I will start with a summary of the main benefits of correlational and case studies, followed by a discussion of the key findings from the few available longitudinal studies.

School capacity for improvement: conditions that support teaching and learning

School capacity for improvement has been defined as a set of conditions at school and teacher level that enable teachers' professional learning, support teaching and student learning and provide strategies aimed at continuous school improvement (Heck and Hallinger, 2009; Mulford and Silins, 2003; Sleegers et al., 2005; Stoll et al., 2006). In conceptualizing school capacity for improvement, scholars have used models in which variation in the improvement capacity of schools is assumed to be a function of the capacities and motivations of workplace personnel (*teacher conditions*), the characteristics of the organizational setting (*organizational conditions, including leadership*) in which they work, and the *external environment* (Leithwood et al., 2002; Sleegers et al., 2014). In these models, leadership practices and school organizational conditions are assumed to have indirect effects on teachers' instructional practices needed for gains in student outcomes through teacher motivation and learning.

Most research in this domain has consisted of case studies and cross-sectional surveys and focused on relating organizational and teacher conditions to instructional practices and student learning in a specific context or at one moment in time. Six sets of conditions at school and teacher level that support teaching and student learning appear to have robust empirical support: leadership, teacher collaboration, participative decision making, trust, teacher motivation and teacher learning. I briefly review these conditions to provide some context about how these conditions are addressed in school improvement research.

Leadership

Leadership is critical in school effectiveness and school improvement (Leithwood et al., 2008, 2020). To understand the role leadership plays in the promotion of school improvement and educational change, scholars investigated specific sets of leadership

practices covered by two dominant models, including transformational and instructional leadership (Hallinger, 2003). Researchers focusing on organizational learning have used transformational leadership models to investigate how leadership practices bring about change. Transformational leaders enhance the commitment, competencies and extra effort of teachers required for organizational change by vision building, providing individual support and stimulating intellectual stimulation. Research in this domain suggests that transformational leadership is related with various conditions for school improvement, including shared decision making, collaboration, teacher efficacy, extra effort, teacher learning and changes in teachers' instructional practices (Geijsel et al., 2003; Leithwood and Jantzi, 2005; Leithwood and Sun, 2012; Thoonen et al., 2011). Those scholars that are more concerned with the *outcome* than the *process* of school improvement, have emphasized instructional leadership as a key construct to study the impact of leadership on teaching and learning. They argue that the primary task of school leaders is to improve instruction as student learning is the bottom line of school improvement. Instructional leaders are goal-oriented, academically focused, coordinate, supervise and monitor teaching and learning and create "academic press" through defining the school's mission, managing the instructional program and promoting a positive school climate (Hallinger, 2005). The large amount of studies conducted in this field has yielded indirect effects of instructional leadership practices on student achievement as mediated by organizational conditions (e.g. school mission and goals, expectations, curriculum).

To better understand and unravel the paths through which school leaders have an impact on teaching and student learning, scholars have suggested to use a more integrated model in which transformational leadership and instructional leadership coexist as the generic functions of leadership practices are often obscured by the use of different styles of leadership (Bruggencate et al., 2012; Hallinger, 2003; Leithwood et al., 2004; Robinson et al., 2008). Research on the influence of integrated leadership on teaching and learning has shown that leadership for school improvement requires both instructional and transformational leadership (Marks and Printy, 2003; Printy et al., 2009; Urlick and Bowers, 2014). Successful school leaders make use of the same basic repertoire of practices, including: (1) developing a vision and giving direction, (2) understanding and developing people, (3) redesigning the organization and (4) managing the teaching and learning program (Leithwood et al., 2006a,b). In line with this, an approach called leadership for learning, also representing a blend of transformational and instructional leadership, has become popular and gained international currency (Hallinger, 2011; MacBeath and Cheng, 2008). Leadership for learning signals, among other things, the critical role that leadership plays in building school capacity for improvement by highlighting the importance of a school-wide focus on learning, both for teachers and students. Based on these multiple leadership frames and available evidence, Hitt and Tucker (2016) recently developed an overarching set of leadership practices for school improvement that accounts for transformational, instructional and leadership for learning. This unified model distinguishes the following five leadership practices: (1) establishing and conveying a vision, (2) facilitating a high-quality learning experience for students, (3) building professional capacity, (4) creating a supportive organization for learning, and (5) connecting with external partners.

The large body of research on the impact of leadership for school improvement has mainly focused on the role of the principal as formal leader. More and more scholars have started to shift the focus from formal leaders to school-wide leadership that is distributed (Spillane, 2006): leadership that is exercised by those in both management (e.g. the principal, assistant principals, department heads) and non-management roles (e.g. teachers, staff). Researchers have found that patterns of distributed leadership (e.g. more or less complex and coordinated patterns) appear to depend on goals and the expertise of those who provide leadership (Harris et al., 2007). Evidence from studies indicates that some of the above mentioned basic set of leadership practices, including developing people and managing the instructional program, are more distributed than the others (Day et al., 2010; Hulpia et al., 2009; Leithwood et al., 2010). Setting directions and redesigning organizations are practices that are mostly carried out by those in formal management roles. Moreover, findings suggest that various patterns of distributed leadership affect school capacity for school improvement and support teaching and learning (Leithwood et al., 2006a,b; Lu and Hallinger, 2018).

Teacher collaboration

Cooperative and collegial relationships and open communication provide emotional and psychological support for teachers' work and opportunities for free exchange of ideas and professional learning (Geijsel et al., 2001; Kwakman, 2003; Rosenholtz, 1991; Smylie et al., 1996). Several studies have shown that teacher collaboration is positively associated with teachers' self-efficacy, their organizational commitment, professional learning and can improve, if focused on student learning, classroom practices (Bryk et al., 1999; Louis and Marks, 1998; Rosenholtz, 1989; Smylie, 1988; Stoll et al., 2006). So, teacher collaboration as a school organizational condition can promote organizational and instructional improvement (Darling-Hammond and Richardson, 2009; Hargreaves and Fullan, 2012; Nguyen and Ng, 2020; Shirrell et al., 2019; Slegers and Leithwood, 2010; Stoll, 2009). Research on professional learning communities has underlined the important role of teachers collaborations and interactions for school improvement (Lee and Louis, 2019). In this line of research, teacher collaboration has been interpreted as one of the five dimensions, (together with shared values, deprivatized practice, reflective dialog and a focus on student learning) that constitute a professional community and more broadly as a feature of or embedded in school culture. Findings from studies into schools as professional learning communities indicate that schools with higher levels of teachers collaboration and norms of collegiality are associated with higher levels of improved instruction, data use and school performance (Leithwood et al., 2001; Earl and Katz, 2006; Smylie and Wenzel, 2003; Coburn and Turner, 2011). By focusing on the importance of social ties and social relationships among teachers, social network theory and methods have supplied some needed specificity to delve more fully in teachers' collaboration as an organizational condition for school improvement. Research on social networks in schools suggests that the patterns of social relationships among educators that result from teachers' interaction promote teachers' motivation (collective

efficacy) and matters for different outcomes (e.g. innovative climate and student learning) of school improvement (Moolenaar et al., 2011, 2012; Moolenaar and Sleegers, 2010; Sleegers et al., 2018).

Participative decision making

Participative decision making is assumed to foster teachers' commitment to change and reinforce their motivation. Participation in decision making refers to joint decision-making or shared influence in decision-making by school leaders and teachers. When teachers participate more in decision making they receive more feedback and create more opportunities to exchange new knowledge and skills and to experiment. Research has shown that teachers' participation in decision making is positively related to teacher motivation (Geijssel et al., 2009; Rosenholtz, 1989; Thoonen et al., 2011), improved teaching (Smylie et al., 1996), their acceptance of policy (Smylie, 1988), and is important for schools' policy-making capacity (Sleegers et al., 1994). As such, participation in decision-making may provide standards teachers can use to evaluate their own practice and clarify school goals. Despite the positive impact on teachers' work, participation in decision-making appears to be contingent on conditions in schools. For example, teachers working at schools with a high innovative capacity participate more in decision making than teachers working at schools with a low innovative capacity (Geijssel et al., 1999; Van den Berg and Sleegers, 1996b). Moreover, teachers are willing to participate most in decisions that are related to the curriculum and instruction, while they are least willing to participate in decisions about personnel and managerial issues (Bacharach et al., 1990). So, a lack of connection with the technical core of teachers' work appears to be an important hindrance for many teachers to become engaged in participative decision-making (Marks and Louis, 1997).

Trust

Trust among organizational members is considered an important emotional or normative resource for school improvement (Bryk and Schneider, 2002; Coburn and Russel, 2008; Forsyth et al., 2011). Trust emerges from social interactions among organizational members and can refer to an individual emotional state that may be shared by others (relational trust) or a norm that is socially constructed by group members (collective trust). Trust is often associated with organizational climate, group cohesion, collaboration and the school culture and facilitates collective action (Adams and Forsyth, 2013). Positive social interactions may create a safe environment and foster trust by reducing uncertainty about the engagement of the other party and establishing a tolerance for failure without the fear of being punished or ridiculed (Bryk and Schneider, 2002; Lipshitz et al., 2007). Research has indicated that densely connected social networks in schools increase teacher trust, which in turn facilitates a more innovative-supported school climate (Moolenaar and Sleegers, 2010). Trust is also positive related to teacher professionalism and teachers' willingness to contribute to organizational goals (Penuel et al., 2007; Smylie and Hart, 1999; Tschannen-Moran and Hoy, 1998; Tschannen-Moran, 2001, 2009). Moreover, trust contributes to improved classroom practice and the performance of schools (Bryk and Schneider, 2002; Goddard et al., 2001, 2009; Tschannen-Moran, 2014). By keeping the professional learning community together, trust facilitates the continuous improvement of schools which may lead to less rigid responses to high-stakes accountability pressures (Daly, 2009).

Teacher motivation

Among teacher conditions that support teaching and learning, teacher motivation plays an important role (Geijssel et al., 2009; Thoonen et al., 2011). Motivational processes are a function of one's personal goals and beliefs about one's capacities and one's context and are aimed at helping the person to evaluate the need for change or action (Ford, 1992). In research on teacher commitment to change a strong belief in and acceptance of the organization's goals and values is often considered as an element of teacher motivation (Geijssel et al., 2003; Leithwood et al., 1999). Teachers are more motivated if they have internalized school goals and values as their personal goals. In setting where there are challenging personal goals, individuals are like to develop a positive sense of self-efficacy (Bandura, 1986). Self-efficacy is an important motivational construct: it is a future-oriented belief about the competence a person expects to display in a given situation. Self-efficacy can strengthen teachers in pursuing action and may take away fear of failure (Bandura, 1986; Geijssel et al., 2009). For example, teachers with higher levels of self-efficacy challenge themselves to reach more challenging goals, will persist in pursuing their interest and actions when faced with obstacles, have less fear of failure, and will find satisfying solutions (Bandura, 1997; Schwarzer and Hallum, 2008). Research has shown that both teachers' internalization of school goals into personal goals and their self-efficacy beliefs affect instructional practices as mediated by teacher learning (Geijssel et al., 2009; Thoonen et al., 2011). Of these two motivational factors, teachers' sense of efficacy appears to be the most important for explaining teacher learning and instruction.

Teacher learning

Scholars have emphasized that professional learning embedded in schools is crucial for school improvement (Clarke and Hollingsworth, 2002; Kwakman, 2003; Putnam and Borko, 2000; Sleegers et al., 2005). Research on organizational learning in schools suggest that learning among staff as well as the development of the school as a whole depend on the opportunities schools create for teacher's professional learning (Sleegers and Leithwood, 2010). Scholars have distinguished different professional learning activities that can promote school improvement (Kwakman, 2003; Lohman and Woolf, 2001; Oude Groote Beverborg et al., 2015a).

These professional learning activities vary from individual activities aimed at acquiring new knowledge, skills, and information, where other colleagues are not necessarily needed, to social learning activities requiring others. Examples of individual learning activities are self-reflection, keeping up to date, and experimentation, while sharing information and asking for feedback are examples of social learning activities. Research has shown that both individual and social learning activities affect instruction (Garet et al., 2001; Geijsel et al., 2001; Supovitz, 2002; Thoonen et al., 2011). Teachers engagement in professional learning activities is facilitated by motivational factors of which self-efficacy is the most important one. Moreover, self-efficacy mediates the relationship between leadership practices, organizational conditions and teacher learning. These findings demonstrate how the interplay between leadership practices, organizational conditions and teacher's motivation affect teaching learning and instruction.

Building school capacity for improvement: changes and journeys

Knowing which set of conditions of school capacity for improvement matter for teaching and student learning is not the same as knowing *how* schools can build their capacity for continuous improvement. Because school improvement involves change in the state of different set of conditions supporting teaching and learning, longitudinal research is needed that take into account the changing relationships between these conditions (Hallinger and Heck, 2010; Thoonen et al., 2012; Slegers et al., 2014). Scholars have therefore started to conduct longitudinal research to examine the causal and reciprocal relationships between conditions that comprise school capacity for improvement, teaching and student learning over time. For a systematic review of the methods and designs used in this line of research, I refer to Feldhoff et al. (2016).

Changes and reciprocal effects

Longitudinal research indicates that school capacity for improvement can develop over time (Heck and Hallinger, 2010a,b; Thoonen et al., 2012). For example, in a longitudinal study of a large sample of Dutch elementary schools, Thoonen et al. (2012) investigated the increase or decrease of school capacity for improvement over time. They found that leadership practices, organizational conditions, motivational factors and teacher engagement in learning activities showed a development over time, both positive and negative. While leadership practices and organizational conditions gradually increased over time, motivational factors and teachers engagement in learning activities barely improved or even become less during the years. Moreover, the "momentum" on which the variables show improvement differs: leadership appears to improve at an earlier point in time than school organizational conditions, teacher motivational factors, and teachers' engagement in professional learning activities.

Building on this work, Slegers et al. (2014) examined the relationship between changes in the improvement capacity of schools and changes in teachers' classroom practices over a four years period of time. The results showed that teachers' classroom practices changed over time and that teachers succeed in sustaining their improved instruction. In addition, motivational factors and teacher learning had the greatest impact on changes in teachers' classroom practices, while leadership and organizational conditions were particularly important in enhancing teacher's motivations and learning.

Based on a large random sample of US elementary schools over four years, Heck and Hallinger (2009) investigated the effects of change in distributed leadership and school improvement capacity on student performance. They found that changes in distributed leadership and the improvement capacity of schools have significant impact on growth in student learning in reading and math. Furthermore, the findings indicate that the effects of change in distributed leadership on growth in student learning is mediated by change in the school improvement capacity.

These findings shed more light on the nature of the causal relations and the interaction over time between leadership practices and different conditions for improvement that support teaching and student learning. However, they do not provide evidence in support of possible reciprocal relationships between these variables and how they mutually shape each other over time. Although scholars have emphasized the need to use reciprocal effects models in school improvement research, little progress has been made so far. A notable exception is the work of Hallinger and Heck. They analyzed the reciprocal relationships between distributed (or what they call collaborative leadership), school improvement capacity and growth in student math and reading achievements (Hallinger and Heck, 2010; Heck and Hallinger 2010a,b). The findings support the reciprocity between collaborative leadership and school improvement capacity. The effects of changes in leadership on changes in school improvement capacity appeared to be smaller than the effects of school improvement capacity on leadership over time. Moreover, changes in collaborative leadership and school improvement capacity were related to growth in student achievement and vice versa. Regardless of the level of student achievement, schools can thus improve student learning by changes in leadership practices and improvement capacity.

Findings from a three-wave longitudinal study of a large sample of Vocational Educational Training Colleges in the Netherlands, showed that leadership practices and teacher collaboration mutual influence each other over time (Oude Groote Beverborg et al., 2015b, 2020). Moreover, some evidence was found for the reciprocity of teacher collaboration and teachers' engagement in learning activities, especially self-reflection. Self-efficacy appeared not to play a pivotal role as a psychological lever between leadership and teacher learning as found in cross-sectional studies. However, a reverse effect was found: self-reflection as an individual learning activity had a positive influence on self-efficacy over time.

Journeys

Rather than focusing on changes in the average improvement capacity among a sample of schools, researchers have recently started to investigate differences between schools' improvement trajectories (i.e. stable, improving, declining) over time. Analyzing these school improvement journeys helps to reveal how building school-wide capacity is situated in the school improvement context. Hallinger and Heck (2011) were able to identify three school trajectories based on student growth in math achievement over a period of 4 years. The results suggest that the positive relationships between change in leadership and capacity building is stronger in schools with the highest student growth over time than in schools with moderate and small growth in student achievement. In their 3-year mixed-methods national study, Day et al. (2016) found evidence for four broad improvement phases: foundational, developmental, enrichment, and renewal phases. These different phases contained different combinations of leadership practices, ranging from attention to "basics," making the school more student-centered to distributed leadership. Based on teachers' perceptions of the improvement capacity of 1200 elementary and middle schools in the New York City context between 2017 and 2019, during COVID-19, Duff (2021) found six types of schools through Latent Class Analyses: versatile, collaborative, developing, balkanized, controlled and demoralized (see also Duff and Bowers, 2021). The findings also showed that schools moved from one type to another between 2017 and 2019, reinforcing that school improvement capacity is not fixed. This typology and the increase and decrease of the improvement capacity was supported by the qualitative case studies conducted. Moreover, the case studies provided strong support for the critical role leadership plays in the school improvement journeys and that the improvement capacity helps schools to manage both internal and external change, particularly to overcome the pandemic's challenges.

School improvement as a system-wide phenomenon

Much of the empirical work on school improvement has used the schoolhouse as the unit of analysis and focused on how leadership practices, organizational conditions, motivational factors and teacher learning support teaching and student learning inside schools. The work of improving teaching and enhancing student learning is not solely the province of school leaders and teachers as schools are part of school systems and embedded in a broader educational environment that provides legitimacy, essential resources and support (Cohen et al., 2018). The organization and the working of school systems and the broader educational environment are consequential for building school-wide capacity for improvement. Many aspects of the school improvement context are shaped by all kinds of design efforts often mandated by political and policy initiatives and guided by an institutional logic aimed at the pursuit of excellence and equity. Focusing narrowly on school capacity for improvement without taking the broader educational environment in which schools are embedded into account misses the array of influences mutually reinforcing system components and actors operating at various system levels may have on building school-wide capacity for continuous improvement (Cohen and Moffitt, 2010). Some scholars have paid attention to how districts, superintendents or school boards may foster school improvement inside schools. There is some evidence that local education authorities and superintendents can support leadership and the improvement capacity of schools and, in turn, affect teaching and learning by district-wide, job-embedded professional development, using data for organizational learning and accountability, and a district-wide focus on educational goals and student achievement (Daly et al., 2017; Hooge et al., 2019; Leithwood and Seashore-Louis, 2011; Lee and Louis, 2019; Louis, 2015; Saatcioglu et al., 2011; Togneri and Anderson, 2003). More recently, a small but growing body of research on network-based educational improvement examines the organizational dynamics of exploration and exploitation as the core learning processes in school improvement networks—characterized by a general hub-member network form—as a strategy for improving education (Glazer and Peurach, 2013; Peurach, 2016; Peurach et al., 2018). Findings from this research suggest that, although some school improvement networks are successful in creating highly developed capabilities for managing and organizing instructionally-focused continuous improvement, success is not the rule. Furthermore, the findings indicate that a system-level innovation infrastructure which is strong in support for evaluating impact, but weak in support for continuous improvement provides uneven support for developing the learning dynamics in networks that have the potential to enhance school capacity for continuous improvement.

However, scholars have devoted little attention to the paths and mechanisms through which the institutional environment can incentivize and resource school systems to build and (re)design their educational infrastructures to coordinate and enable instructional improvement. One of the key challenges for school improvement research is to understand how the interrelationships among resources, processes and (system and non-system) actors, operating at various levels, from schools to school systems and the broader educational environment, work in tandem in an effort to support school wide capacity for continuous improvement (Cohen et al., 2018). Research on school improvement would profit from using a more systemic approach that focuses on the interaction between leadership, school improvement capacity, school systems and networks and how these linkages constitute instructionally-focused continuous improvement, while taking the broader institutional system in which schools are embedded as the relevant unit of analysis (Cohen et al., 2018). Hence, scholars should frame school improvement as a system-wide phenomenon and investigate the dynamics and complexity of school improvement from a systematic perspective by drawing on system thinking and complexity theory (Schechter and Shaked, 2018; Slegers et al., 2018).

Conclusion

In this chapter I reviewed the large amount of research on school improvement and argued for framing school improvement as a system-wide phenomenon. By using two views, the internal and external view, that underlie the different perspectives scholars have used to examine school improvement, I brought together key findings of school improvement research from the lens of school improvement capacity. Robust empirical support evidence has been found for a set of conditions comprising school capacity for improvement that support teaching and student learning: leadership, teacher collaboration, participative decision making, trust, teacher motivation and teacher learning. Findings from the available longitudinal studies also suggest that school capacity for improvement fluctuates over time and seems to be malleable. While leadership appeared to play a critical role as a driving force for school improvement, leadership and school improvement capacity mutual influence each other to support teaching and student learning. By revealing the variation in change trajectories, studies into school improvement journeys indicate that all schools and not only the poor performing school have to be engaged in building school-wide capacity to improve teaching and learning.

Although substantial progress has been made, I argued that scholars should look at school improvement from a systematic approach. Using a multi-dimensional systemic framework would help school improvement research to focus on the dynamic changes between conditions at school and teacher level that support teaching and learning and the social interactions, patterns and networks between actors and schools at different levels of the educational system that support school-wide capacity for continuous improvement. This may result in a fruitful attempt to synthesize the diverse theoretical perspectives on school improvement into a single overarching conceptual framework and help us to better understand the complexity and dynamics of school improvement.

Future directions for research can be derived from the weak spots of theoretical perspectives and empirical evidence. Key issues for research are to examine and explain how large-scale reforms at the macro-level and patterns of instructional organization and management within and between school systems at the meso-level interact to shape school wide capacity for continuous improvement. Future research should also focus on how change can be sustained over time and how reforms can be extended to more teachers, schools and districts. Little empirical evidence exists for differences between educational systems around the world and how these differences contribute to differences in the practice of leadership and the improvement capacity of schools to support teaching and learning. To unravel the complexity and dynamics of school improvement, researchers should use different designs (e.g. longitudinal designs, comparative research designs and design-based implementation research) and mixed methods to gather rich, dynamic, contextual and longitudinal data. Findings from these studies will help us to deepen our understanding of how schools that are embedded in an educational system can build school capacity for continuous improvement. Findings from these studies may also help us to develop a theory of design that can provide practitioners with tools to redesign and change system mechanisms that constrain and enable school capacity for continuous improvement.

Introduction

Attempts to improve schooling and better prepare students have persisted as long as schools have existed. This ameliorative intention has translated into the development, adoption, and implementation of a wide variety of reform efforts, from those that focus on one or two aspects of classroom life to comprehensive efforts that affect classrooms, schools, districts, and even national policy.

We have been studying the school reform process primarily by engaging in qualitative research. Our studies have involved hundreds of interviews with district leaders, principals, teachers, and parents throughout the United States. We spent hours conducting observations of classrooms and professional development events organized to support educational leaders and teachers, and we have examined community factors external to the school to understand their contribution to the shaping of reform.

Our research has taken a constructivist orientation that focuses on the dynamic interplay between culture, structure, and agency. These studies have led us to examine the role coherence and leadership plays in reform. When cultural and structural coherence is present, reform efforts benefit from educators sharing a common language and beliefs about the reform. In contrast, when coherence is absent, the possibility of a reform being successful is often challenged. Each of the cases we discuss here also illustrate the important role leadership plays in affecting reform outcomes. Models of school leadership vary from top-down mandates to “distributive collaborative” models, which are models that offer a more responsive and inclusive set of conditions (Diamond and Spillane, 2016; Woods and Roberts, 2019). Each leadership model defines meaning and mediates educators’ action—either supporting or pushing against the proposed reform.

We begin with a discussion of our theoretical frame and then describe each of the cases of reform change through this lens. By depicting culture, structure, and agency as equal participants in a reflexive system of social action, we gain better insight into the processes that facilitate or constrain school reform efforts.

Culture, structure, and agency: components of a constructivist theory of school reform

Our constructivist position regards reform policy as an ongoing process of negotiating meaning in real-life educational settings. Politically, reform policy is a mechanism for powerful actors to manage contested perceptions by focusing attention on some conditions rather than on others and by promoting a particular interpretation of those conditions. It is also a means for powerful actors to legitimate particular meanings by granting them the authority derived from these actors’ official statuses. Finally, policy works to shore up institutional authority by communicating an institution’s commitment to particular values and ideas.

The constructivist perspective contributes to public policy theory by reinforcing the idea that public policy is both a process and a product of constitutive human activity (Datnow et al., 2002; Hall, 2017a,b; Hall and McGinty, 1997; Hubbard et al., 2006; Mehan, 2012). As a *process*, policy is a means by which statements of value and definitions of reality are constructed, asserted, validated, and negotiated. As *products*, policies are the material residues of these actions. They are cultural objects and artifacts that “embody the

authority to define goals and command means" (Levinson and Sutton, 2001, p. 5), legitimize and reinforce particular views of reality, and grant those definitions some form of "official" (i.e., institutionalized or publicly recognized) status.

Leaders often construct reform policy—the reform process and the products—but policy studies often assume leadership and decision making occur first at the top of a hierarchy. The implication is leaders at the top are more analytically important (Pressman and Wildavsky, 1973; Ravitch, 1995; Smith and Keith, 1971; Tucker and Coddling, 1998). By contrast, the constructivist position does not automatically assign an *a priori* importance to any one hierarchical context, including those at the top of a hierarchy. Instead, it recognizes leadership can be distributed across key agents (Diamond and Spillane, 2016). Woods and Roberts (2019) expanded notions of distributed leadership by emphasizing leadership can also be a collaborative process constructed both from the intentions, emergent actions, and ideas of leaders and other educators.

Our constructivist approach to understanding educational reform also takes into account the influence of reform coherence—the extent to which a reform has been created to ensure consistency within and across schools. According to Fullan and Quinn (2016), coherence can allow educators to share a "depth of understanding about the purpose and nature of the work" (p. 1). When teachers and leaders individually and collectively cohere, they are "focusing direction, cultivating collaborative cultures, deepening learning and securing accountability" (Fullan and Quinn, 2016, p. 12).

An earlier school improvement study of Chicago schools showed elementary schools with stronger program coherence had higher gains in academic achievement (Newmann et al., 2001). "Instructional program coherence," as defined in this study, included a common instructional framework supported by conditions and practices that avoided other competing improvement efforts. Coherence assists teacher effectiveness because teachers work with other teachers in an integrated manner (Newmann et al., 2001). As Cohen et al. (2017) pointed out, however, the pressure to build coherence pushes against a legacy of incoherence in schools and environments. Efforts to build consensus are challenged by those who support differentiated outcomes and methods. As open systems, schools must respond to parents and community members and navigate political pressures.

At the level of whole school and/or district-wide change, building coherence involves respecting and building upon teachers' professional wisdom (Datnow and Park, 2019). We know, for example, teachers are not passive adopters of reform. They may resist, comply, or adapt. Even when they believe in the reform, teachers often modify a reform by exerting their judgment, in many cases to respond to the diverse needs of their students. District-level coherence can facilitate school improvement as well, but, more often, districts keen on improving academic achievement adopt multiple initiatives. If these initiatives lack a coherent fit, teachers are confused and feel overburdened with the demands of each reform (Hubbard et al., 2014). Conflicting program goals can challenge implementation coherence and "conflict with those [programs] currently in place in local school communities" (Madda et al., 2007, p. 1959). Investigating coherence provides additional insight into factors that support or challenge reform success.

The value of "teacher buy-in" when introducing reform

In this section, we describe how a comprehensive reform played out in San Diego City Schools (SDCS) from its inception in July 1998 to August 2002. We examine the cultural and political clashes that erupted within the district, and between the district and valued constituencies, to shape reform outcomes. The reform was notable for its attention to the structural and cultural dimensions of the reform, while minimizing the role of agency within the organization. Although reform leaders attended to the actions of philanthropists and actors in positions of power, they paid less attention to actors "on the ground" (i.e., teachers, principals, and community members). This lack of attention to those most intimately involved in adopting and implementing the reform contributed significantly to the premature demise of this ambitious reform (Hubbard et al., 2006).

To achieve the reform's goal of improving student learning, district reform leaders installed *The Blueprint for Student Success*, a content-driven, centralized, comprehensive, and fast-paced reform starting in 1998. This plan was put forth to ensure there was coherence across all schools in the district. The most notable structural features emanated from centralized leadership in which major instructional, operational, and professional development decisions originated from the top of the district while administrators at school sites, staff developers, and resource teachers were tasked with implementing plans designed by the superintendent and "chancellor of instruction."

The district leadership attempted to "reculture" the SDCS by organizing educators into *communities of practice*, moving teaching from private to public practice, and transforming operational managers into "instructional leaders." This reculturing and push against the taken-for-granted grammar of schooling (Tyack and Cuban, 1995) involved developing common thoughts, beliefs, and a common language about skills, practices, and accountability among educators in every part of the school system to reach the district's goal, which was to improve student achievement by supporting teaching and learning in the classroom.

The district's centralized, fast-paced, and comprehensive reform was legitimated on moral and political grounds. Comprehensive, simultaneous, and centralized implementation was legitimated morally by saying significant numbers of students could not be asked to wait until an entire system was ready to provide them with the support they needed to learn. Their theory of action was legitimated politically by saying piecemeal modifications were all too often absorbed by the system and therefore did not lead to paradigmatic shifts. The SDCS' investments in instruction and professional development were legitimated by claiming these changes in professional practices rested on a well-established, empirically supported disciplinary knowledge base.

Reculturing teaching practices

Prior to the move to systemic reform in the mid-1990s, teachers were generally regarded as autonomous agents. Teachers were relatively free to assemble the curriculum and instruction they enacted in their classroom. The SDCS district leaders concluded this “private practice” seldom synchronized and calibrated teachers’ practices across classrooms at one school and across schools within the district, resulting in differences in performance across schools. Instead, SDCS leaders aimed for a coherent system of change designed to create a common set of beliefs and some shared and valued practices visible in all classrooms.

This attempt to “reculture” (Fullan and Hargreaves, 2012; Hargreaves, 1994) moved teaching from private practice to communities of public practice. Reculturing involved opening classroom doors to principals’ and coaches’ scrutiny, working collaboratively with peers to solve common problems, and developing common thoughts, beliefs, and language about skills, practices, and accountability. Many teachers—following the lead of their union—resisted these changes in their practice because they challenged their beliefs that they had earned autonomy, or the right to teach as they saw fit. Teachers and union leaders especially resented calls for changes in teaching practice because they were designed and implemented from the “top down” without consulting teachers. Resentments turned into clashes.

Another significant reform move that clashed with teachers’ beliefs about their instructional roles was generated when reform leaders directed high school principals and their teachers to teach reading strategies. High school principals and teachers insisted they knew how to teach biology, algebra, English literature, and other subjects, but they neither knew how nor wanted to teach reading strategies. Elementary school teachers should teach reading, they insisted, not high school teachers. Furthermore, whereas the elementary school calendar enabled extended learning time for literacy, the high school calendar that scheduled classes into discrete time periods worked against the extended learning time needed for improving students’ reading skills.

Many teachers and teachers’ union leaders who opposed the reform said it was their job to teach—to present the material; it was students’ responsibility to learn—to “get it.” If students did not get it—then it was students’ fault; it was not teachers’ responsibility to change instruction to meet students’ needs.

The SDCS reform leaders countered that all children can learn and that it is teachers’ responsibility to find the means to actualize this basic principle of the reform. This idea—that teachers’ high expectations and instruction can improve students’ academic performance—challenged the idea that social factors outside the school, such as students’ impoverished conditions, their lack of mastery over the English language, and their frequent movement between schools, are reasons why students may struggle to learn. Critics of the reform complained the district’s focus on instruction as the means to close the achievement gap did not give enough weight to the influence of students’ social circumstances and instead blamed teachers for students’ failures.

Another set of clashes based in institutional culture erupted over one of the most basic tenets of the reform: Area superintendents and principals should abandon their operational responsibilities and become “instructional leaders.” Instructional leaders became responsible to teach and support teachers in the successful enactment of the reform. This demand challenged some teachers’ and principals’ strongly held beliefs about their leadership role. Moreover, many principals rose through the ranks on the operational and administrative side of the district and were not prepared to coach all teachers in all subjects.

Political clashes between the district and valued constituencies

The district’s theory of action that placed instructional change on the leading edge of the reform agenda generated conflict within the district and between district leaders and valued constituencies. While these structural changes and commitments to raising student achievement won the district leadership the support of the powerful local business community, the national press, and granting agencies, it did not secure teachers’ buy-in or win significant union, community, or unanimous school board support. The resulting political and cultural conflicts, combined with a devastating state budget crisis, led the SDCS in new directions.

In promoting the progressive ideal of closing the achievement gap, the district leadership called attention to the poor performance of students in low-income neighborhoods who tend to have teachers with the least teaching experience and the least professional qualifications (e.g., degrees and credentials). In response, they allocated significant material resources to these “focus schools.” Exposing these “social facts” was intended to rally the community, especially parents of color, by admitting the public school system had not served their children well and by encouraging support for a more rigorous curriculum and higher quality instruction.

These rhetorical moves spawned an unfortunate side effect, especially among some members of the teaching corps, however. Teachers felt they had been unfairly blamed for the achievement gap, and some parents and students agreed with them. Adding to this perception of blame was a perception of disrespect—that local teachers’ knowledge did not count; only the expertise of people from New York City (the prior home of the “chancellor of instruction”) and New Zealand (the home of the literacy program adopted by SDCS) mattered.

While supporting the structural aspects of the reform through increased funding and new construction, parents in San Diego’s affluent neighborhoods lambasted the pedagogical dimensions of the reform. They said the new structure of 2- and 3- hour literacy blocks watered down high school instruction, forced more valued elective courses from students’ courses of study, and restricted teachers’ creativity. A coalition of wealthy parents and teachers exercised their social capital and negotiated concessions from the district over these complaints. A high school in an affluent neighborhood was granted “pilot” status, which exempted the school from conformity to the reform after a coalition of parents and teachers threatened to form an independent charter school. Their actions began to erode the reform leaders’ plan for a coherent comprehensive reform.

Parents and community activists in San Diego's less affluent and predominantly ethnic neighborhoods voiced different concerns than their more affluent contemporaries, albeit no less stridently. The "Latino Coalition," one particularly vocal group within the Latino community, supported the *Blueprint* reform for 18 months because of its promise to close the achievement gap, but the coalition withdrew its support in the fall of 2000 because their leaders said the reforms were not meeting the needs of English language learners, leadership profiles did not reflect the diversity of students in the district, and the district was diminishing due process and respect for parents (Latino, 2001).

In addition, a combination of community groups, supported by the board minority, accused the district of making administrative decisions "top down" without parent or community consultation. Whereas parents in affluent neighborhoods traded their social capital for concessions from the district, when parent and community groups in less affluent neighborhoods were not able to do so, they resorted to walkouts, lawsuits, and appeals to the US and California Secretaries of Education. None of these actions were successful, however.

Summary

The SDCS district's attempt to introduce this coherent, wide-ranging, and innovative reform produced unintended consequences. Introducing innovations into complex systems such as school districts is unpredictable because the existing system pushes back in sometimes predictable, sometimes mysterious ways. "Push back" rooted in organizational culture—including the agency of the educators within the organization and those embedded in community politics—contributed to the premature demise of this innovative reform.

The culturally based reason for resistance to proposed innovations concerned the conflicting meanings teachers, principals, instructional leaders, community members, and reform leaders attributed to new norms, beliefs, and standard operating procedures. The district leaders' desire to convert the area superintendents' and principals' roles from operational to instructional, transform all their teachers into literacy instructors, and make teachers' practice public not private collided with many teachers' and union leaders' long-standing and deeply held beliefs about leadership and teaching roles.

Findings on the underutilization of the expertise of actors on the ground are especially troubling in light of the literature on the importance of "teacher buy in" or "relations of trust" (Bryk and Schneider, 2003) for successful school reforms. Datnow (2000) concluded new programs are not successful without meaningful involvement of teachers in their adoption and implementation. The process of reform initiation, Datnow said, echoing Fullan (1991), is as important as the reform itself. There is a world of difference, between compliance with the parameters of a particular solution and genuine support for its principles (Datnow, 2000; Hubbard et al., 2006).

District leaders invested more heavily in building political alliances with powerful community and national groups than they did in cultivating "buy-in" with educators up and down the line. As a result, the local teachers' union, a vocal school board minority, and advocacy groups based in well-to-do and less-well-to-do communities voiced loud and consistent opposition to the district's content-driven, comprehensive, and centralized reforms. The reform design team took a calculated risk that a fast-paced, centralized reform would transform instruction that, in turn, would produce positive gains in student performance. This evidence would then convince all concerned about the efficacy of the reforms. The short unhappy life of the reform suggests this bet did not pay off.

Schools and reform design teams co-construct reform

A well-documented finding in studies of educational reform is that schools modify reform models as much as, if not more than, reform models change schools (Cuban, 1998). As the examples we present have shown, however, these accommodations are not necessarily the result of recalcitrance, resistance, or ignorance of educators in local school sites. Conditions in local contexts cause educators to modify reform models to better suit their needs. Some adaptations are rather benign, other adaptations enhance reform designs, whereas others threaten the intensity and potential success of the reform.

Achievement Via Individual Determination (AVID) is an educational reform program designed to narrow the achievement gap between socioeconomic and ethnic groups. AVID promises to improve the achievement of low-income and minority students and increase their chances of attending college by offering them a more rigorous college preparatory high school curriculum accompanied by a special college-prep class.

The implementation of the AVID college preparatory program in California, Kentucky, North Carolina, and Virginia was not only influenced "top down" by the actions of AVID's design team; the actions of the design team was also influenced "bottom up" by the actions of educators in schools, as well as by other forces existing in different layers of the system (Datnow et al., 2002).

An example of a design team changing in response to a combination of political actions initiated by the state and pressures from local constituents occurred when AVID redefined its student population. From 1980 until 1995, AVID said it recruited low-income students with high academic potential from ethnic groups historically underrepresented in colleges and universities. AVID changed its way of representing students, partially in response to the elimination of affirmative action, first by the UC Regents and then by California voters, and partially in response to sentiments expressed at new school sites, especially in Kentucky and Virginia. Although changes in California state law that eliminated affirmative action did not directly affect AVID, the leadership felt AVID would be on safer ground to no longer mention race or ethnicity in its program statements. Instead, AVID changed the representation of the student population it serves. AVID now says it provides college prep services to "students in the middle."

Local political pressures in Kentucky and Virginia reinforced the need for AVID to redefine its intended student population. Educators in high schools beginning to implement AVID recoiled from depicting AVID students in racialized terms. Doing so, they said, would offend White parents and community members who would see AVID as engaged in reverse discrimination. More fundamentally, AVID's reform model challenged entrenched cultural beliefs about academic success and the distribution of intelligence and ability along racial lines. AVID's policy to place underrepresented minority students in college prep courses, however, met resistance from some educators and community members who believed intelligence is fixed, natural, and racially based. They said Black and Latino students lacked these skills. These long-standing and deep-seated cultural beliefs in schools throughout the study sites had led to tracking practices that excluded Black students from honors and AP courses and left them with fewer opportunities for future academic success than their White peers.

To navigate the oppositional discourse about intelligence, race, and academic achievement, the AVID design team adopted a strategy of accommodation. Rather than retreating from serving schools in Kentucky and Virginia that had requested their services, AVID redefined their student population just as they had in California. Instead of explicitly taking race or ethnicity into account, they advertised recruiting "students in the middle." When teachers were unable to gain district approval for offering an AVID academic support class during the regular school day, they resorted to offering a "Zero Period" class before the regular school day, or a "seventh Period" after school.

This case reveals two dimensions of school reform efforts: (a) the conditions in local contexts, and contexts far away from local contexts, influence educators to modify reform models to better suit their needs; and (b) cultural beliefs about race and intelligence can become structural constraints impinging upon school reform.

AVID's decision to change the definition of students targeted for admission and to offer college prep courses before or after school was influenced by decisions made in California's government chambers—which are far removed from AVID's schools—and then by local educators in Virginia and Kentucky reluctant to devote class time to a program devoted primarily to underachieving students. Deep-seated and long-standing cultural beliefs about race-based intelligence became structural constraints that threatened to derail this reform effort. Local AVID educators offered support classes at alternative times—actions that salvaged their fledgling programs by working around structural constraints.

The value of coherence in restructuring and reculturing school reform

In 2015, AVID expanded its opportunities to narrow the achievement gap by moving from solely a middle and high school program to a program for elementary schools. AVID created "AVID Elementary" (AE), a schoolwide program that created a structure and culture intended to motivate students to begin to think and prepare for an academic path that would eventually qualify them for college admission.

In a recent study of AE in six schools across the United States, we found each school was expected to be structurally and culturally coherent across all grade levels within the school and coherent with all other AE schools within the larger AVID Program (Hubbard, 2019; Hubbard et al., 2022). AE educators are expected to adhere to the AVID Essentials by embedding a specific set of instructional practices.

Understanding reform as a co-constructed process—that is, taking structural and cultural factors into account—is clarified when considering the role coherence plays in shaping reform. The AE reform achieved coherence through a centralized and comprehensive professional development (PD) system, primarily through district trainings and national summer institutes. Each year, more than 40,000 educators gather at one of 12 institutes across the country for AVID's premiere training event. Districts also host their own AVID PD often with members from AVID Central.

Structural coherence in AE schools is achieved through the use of common educational tools. AE teachers cohere around instructional practice by implementing common pedagogical strategies such as collaborative groups, philosophical chairs, and Socratic seminars. For example, teachers in every classroom use writing, inquiry, collaboration, organization, and reading (WICOR) strategies across the curriculum. Every AE school has a site team with a lead teacher who organizes ongoing instructional training for all teachers across all grade levels (Hubbard, 2019; Hubbard et al., 2022).

Elementary schools traditionally have focused on a school curriculum that gives little, if any, attention to college. By contrast, AE attempts to *reculture* a school by shifting expectations and beliefs among teachers about the necessity of preparing students for college and career. School site teams help to support this goal by creating a common language shared by all teachers, empowering and creating opportunities for teacher collaboration. Teachers across grade levels work together routinely to reflect and revise their practice and create new strategies to push the work deeper. All principals and school counselors are expected to attend their own AVID trainings to enable them to support the structural and cultural changes required to support the goals of AE.

District coherence matters

The role of the district is always important in the success of school improvement. This axiom proved to be true for the schools in our study as we examined the success of AE's adoption, implementation, and the ongoing support they received to meet their immediate and long-term goals. District, school leaders, and teachers pointed to the important distinction they made between districts "*with AVID*" (an attitude that we have the AVID program) and "*an AVID district*" (an attitude that AVID is what our district is about). When AVID is districtwide and the district is all about AVID, there is a high level of support for AE. When district leaders offer

a greater sensitivity to making sure principals and teachers are clear on how AVID fits with the overall vision of the district and filter any other initiatives that might prevent them from deepening the work of AE, AE seems to run more smoothly. Teachers were taught how they could use their AVID strategies to respond to the goals of other district reform initiatives. Moreover, district leaders explained they would only adopt an initiative if it was consistent with the AVID mission. District leaders committed to AVID took actions to ensure all other reform initiatives created a consistent message and a consistent ideology that put AVID first.

Coherence broke down at the district level in some districts, however, when AE students attempted to transition into an AVID elective in middle school. Students found they were blocked from participation because too few sections of the AVID elective class were available to them. Realizing middle schools students want to have the opportunity to take a variety of electives, middle school principals opted instead to offer an elective “wheel,” an arrangement where AVID is only one among several electives rather than scheduling multiple sections of AVID.

In response to the limitations of the wheel approach to elective offerings at the middle school level, AVID Central adopted a new *schoolwide* approach. AVID leaders reasoned, by embedding AVID strategies throughout all classes in the middle school, all students would gain some exposure to AVID’s academic support strategies, even if they missed out on the in-depth intervention a single AVID class would provide. All middle school teachers, ideally, would receive some AVID training so they could implement AVID strategies in their classes.

This approach has had unintended consequences. Depending on the commitment of school educators at each school, AVID is more or less evident, and, as a result, the reform has had varying levels of impact on students’ academic outcomes. AVID calls this interruption in support an example of another “opportunity gap.” Without full participation in AVID in middle school, the likelihood that the typical AVID population of students will seek AVID in high school and continue on a pathway toward college is limited. AVID’s own research shows students need 3 years of participation in the AVID class to outperform their non-AVID peers, and this interruption may derail students.

Summary

The case of AE shows the profound affect schoolwide structural and cultural coherence can have on building and sustaining reform. Moreover, AE is functioning under a leadership model that privileges collaborative professionalism. Principals, teachers, and counselors work together to socialize students into a college-going culture. Common professional development provided by AVID Central helps to build consistent practice at the school and district level. When a reform is institutionalized through the development of common structures, and a schoolwide and district culture is created that motivates educators to cohere around a focused common goal, then reform goals are more likely to be successful. When coherence breaks down, however, at the systems level, due in part to AVID Central’s own middle school approach to participation in AVID, coupled with the unwillingness on the part of middle school principals to adequately support AVID schoolwide, AE students miss educational opportunities to continue with AVID.

Leadership, coherence, and the co-construction of reform

The case of AVID Elementary points to the importance of coherence in the co-construction of educational reform. The next case, a story of school turnaround, reinforces the need for coherence and also highlights the role of collaborative leadership (For more detail on this case, see [Hubbard and Datnow, 2020](#)). A previously underperforming, under-enrolled, urban US middle school underwent a dramatic change when new leadership took over and engaged teachers in a revisioning process. The school restructured into a magnet school that has gained international attention for their innovative practices. In the past 3 years, approximately 1000 educators from across the globe visit the school annually in an attempt to replicate their model. There are now 4 times as many applicants as there are open spots each year.

A new principal began by engaging staff in a reculturing process. Morale among teachers was low, as they had experienced a frequent turnover of principals and felt pressured by accountability measures that did not inspire them or their students. The principal saw an immediate need to include teachers in the visioning for the school and to shift from a more hierarchical model of leadership to an inclusive one. Many honest conversations were held among the then-new principal and the staff, addressing tough topics about student expectations and mindsets. This began the shift toward a school culture that embodied love, respect, and trust for students and teachers alike. With these foundational elements in place, the principal and teachers collaborated to chart plans for instructional improvement.

After a period of much discussion and joint learning, the group decided design thinking (DT) would be at the core of the school’s reform efforts. DT is an instructional approach to increase student engagement, motivate innovative and critical thinking, and teach students to problem solve. DT offers a departure from traditional schooling and emphasizes knowledge construction oriented around real-world problems ([Bereiter and Scardamalia, 2006](#); [Koh et al., 2015](#)). A focus on DT helped build coherence in the school, and staff were provided with an array of professional learning opportunities to learn about and become expert in DT. DT now serves as a focal point and is embodied across the curriculum and in how staff engage in joint problem solving.

A structural element that supported DT was the creation of Design Lab electives. The principal encouraged teachers to create Design Labs built around their own knowledge and passion as well as what would foster student engagement and creativity. Students choose from a menu of innovative offerings, including robotics, architecture, business entrepreneurship, forensic analysis, rocketry, wearable technologies, among others. In these student-centered learning environments, students are exposed to DT. They

identify a problem, develop empathy, ideate, explore potential solutions, and create a prototype or model that displays a solution to that problem. Creativity, innovation, and critical thinking are prioritized, and the memorization and rote learning are eschewed.

While the school staff was committed to offering Design Labs, finding time in the schedule was initially a challenge. Organizational structures like the master schedule often serve as a barrier to change in secondary schools. To make space for Design Labs, staff decided students would have a rotating block schedule, attending odd and even periods on alternating days. The traditional 90 min blocks are split into 50 min Design Lab and 40 min lunch periods every day. Every student participates in a semester-long Design Lab class every day, which is uncommon at the middle school level where students needing remediation often have to forgo electives. An additional elective period for classes such as music or student government still exists as well.

At this school, DT is deliberately not marginalized within the Design Lab electives. Educators realized DT had to be integrated into core content classes, including math, English, science, and social studies. The DT framework allowed teachers and students to share a common language and common practices, engaging students in DT as they interrogate texts, address social problems, or engage in science projects. There is a shared sense of the importance of this instructional model among teachers and principals that allowed DT to spread and deepen. Coherency allows teachers to talk to one another about teaching strategies, and it provides consistency across the curriculum for students.

In everyone's estimation, the school has undergone enormous changes in the past 5 years. Undergoing such a dramatic transformation, however, has taken significant effort and tenacity. First, some teachers initially remained somewhat wedded to their traditional ways of teaching, and this challenge had to be overcome. Teachers were given freedom in how they engaged in change, but the nonnegotiable was they had to better support student learning. Opportunities to build teacher capacity were essential. Many teacher preparation programs do not teach DT or other nontraditional ways of organizing schooling. Educating parents in the community about the school and how it functions is an ongoing challenge. Since nontraditional teaching looks different, educators and parents have also considered students' preparation for high school and more traditional ways of teaching that involve note taking, testing, and considerably less flexibility. Ultimately, staff defended the structure and culture of their school against these challenges, believing it is more important to chart a new path than to prepare students for traditional, outdated learning settings. Fortunately, the district supported the school's efforts as well.

Summary

This case of school reform reveals how educators exercise agency and leadership to transform the structure and culture of the school. The principal was mindful that reform had to be a collective endeavor and that teachers were central to the change effort. The decision to orient the school around DT brought coherence in the educational program for students and teachers. It also served as a way for educators to problem solve when challenges arose. Given that various school features departed from the traditional grammar of schooling (Tyack and Cuban, 1995), it is not surprising the school's structural features received some pushback from teachers and parents accustomed to the usual ways of "doing school." Sustaining change thus requires deep commitment among powerful agents who are willing to stay the course.

Conclusion

The case studies we reviewed here show the value of depicting the reform policy process as a constructed project involving structural, cultural, and agentic dimensions. We learned implementing structures that support change, alongside a process that involves reculturing in which educators begin to share common beliefs about teaching, can facilitate the success of reform goals. These cases also show the actions of educators and leaders matter. The street-level bureaucrats tend to be neither necessarily compliant nor passive actors. Likewise, actors in positions of power are not necessarily seen as rationally and intentionally calculating courses of action and then directing their underlings to implement these plans. Instead, those at the top, those distributed throughout schools, and those at the bottom of bureaucracies are understood to be making organizational choices in situations that involve uncertainty.

By deploying a constructivist perspective, we exposed the impact reform coherence has when it is within and between structure, culture, and agency at *all* levels of the system. It contributes to the success of the policymaking process, and that process is characterized by continuous interactions among social actors within and between levels of organizational systems, such as what happens within and between schools and with district administration.

We reported on cases of social policy, as it was generated in face-to-face interactions among real people who were confronting real problems, in concrete social settings. In the cases we presented, social actors responded to policy directives in a variety of ways—initiating alternatives, advancing or sustaining directives, and resisting or actively subverting them. Most importantly, the agency of and interaction between participants in the educational policymaking process is perceived as being part of a complex dynamic, one that *shapes* and *is shaped by* the structural and cultural features of school and society.

Calls for evidence based decision making have drawn attention to whether and how research is used in school level decision making. Researchers have found that a significant gap exists between the worlds of research and practice (Coburn and Stein, 2010). Some suggest that, in order for research to meaningfully impact practice, characteristics of the research itself must change. Such critics assert that research oversimplifies complex problems (Lather, 2004) or is not written in a manner that is easily digestible for practitioners (Rickinson et al., 2004; Vanderlinde and van Braak, 2010). Others suggest research should be more pertinent to topics that teachers and other practitioners care about (Vanderlinde and van Braak, 2010), or disseminated in a fashion more suited to reaching teachers and leaders (Cook et al., 2013). At the same time, still other studies of research use tell us that it is the practitioners who must change—that they must find the time or the motivation to consume research or would benefit from graduate level courses to deepen their capacity to understand and use research (Ion and Iucu, 2016).

While these suggestions may serve to lessen the gap between research and school level actors, they miss some important contextual layers that mediate practitioners' ability to engage with research. Perhaps we should not isolate the research as the central object, nor the researchers or the practitioners.

We expand on these factors by conceptualizing research use in schools using an *organizational* perspective. By organizational, we mean that we consider the complex contexts within which teachers and school leaders work, and how these contexts facilitate and hinder opportunities to bridge research and practice. Organizational theory delineates how factors inherent to organizations such as schools—and the systems they exist within—influence their functioning. We synthesize findings from existing studies and draw upon organizational theory to build a contextualized conceptual framework that aims to contribute to our understanding of whether or not—and why, and how—educators interact with research. In so doing, we answer the question: what organizational factors and district-school arrangements may influence school actors' use of research? In designing a multi-district study of educators' evidence use in education, our research team developed an original conceptual framework to guide our investigation of school level research use. In this article, we describe this framework and the literature that undergirds it.

To orient you to our conceptual framework, we begin with discussing the existing literature on school leaders' decision making and the use of research within. We then describe key elements of the broader organizational context that we see as influencing educators' decision making process. Understanding whether and how research is used in school level decision making first requires an understanding of the process of decision making within school settings. We then describe the key organizational dimensions that shape the decision making process, and how these dimensions can broaden or narrow the opportunities for educators to engage with research in school settings. Finally, we illustrate how these dimensions dynamically interact in the decision making process to mediate research use in schools. We conclude by suggesting ways that this framework may prove useful to the research community moving forward.

The decision making process in schools

We view decision making as a complex social process (Cohen et al., 1972; Hannaway, 1989; Kennedy, 1982; Majone, 1989; Weiss, 1988; Weiss and Bucuvalas, 1980). In schools, it can involve administrators, coaches, teachers, and other staff members

Fig. 1 Conceptual framework for research use in school-level decision making. Reprinted from Huguet et al. (2018).

(Spillane, 2006). Decision making activities include selecting, (re)designing, and maintaining policies and programs (Weiss and Bucuvalas, 1980). In the process of selecting, (re)designing, and maintaining, decision makers interact in a complex social dance, in which they engage with one another to “recommend, advise, confer, draw up budgets, testify, develop plans, write guidelines, report, supervise, propose legislation, assist, meet, argue, train, [and] consult” (Weiss, 1980, p. 163).

In this view of decision making, decisions are not singular momentary choices, but rather a process of accretion (Weiss, 1988). Decisions are a series of choices and actions connected over time across departments, grade levels, programs (e.g., English learners, special education, general education), and an organizational hierarchy (Hannaway, 1989; Kennedy, 1982; Majone, 1989). In our conceptual framework (see Fig. 1; Huguet et al., 2018, p. 626), the dashed box in the upper right corner of the school level represents the decision making process as it occurs within a school. Each smaller square within this box is a point of deliberation within the process, connected to one another through varied linkages, and not occurring in a predictable or linear manner. These squares represent both planned points of deliberation, such as meetings, and casual conversations in school hallways and classrooms.

Some decisions may seem to be made by an individual, such as a teacher making an instructional decision for their classroom. If we unpack the teacher’s decision making process, however, we see that even these decisions are influenced by interactions with other people inside and outside of their school. An individual teacher’s decision may be influenced by decisions made within the teacher’s team, school leaders’ instructional decisions, guidance provided by central office leaders, and events occurring in students’ communities (Gamoran et al., 2000).

The use of research in decision making

We understand research as an activity or product of an activity in which people employ systematic, empirical methods to answer a specific question. Research might be conducted by university researchers, but is also undertaken by others, such as district officials or practitioners within schools. Investigations may draw upon qualitative, quantitative, or mixed methods. Research can appear in books, academic journals, practitioner-oriented journals, and in policy and evaluation reports developed by researchers within a district (Penuel et al., 2016).

By focusing on research, we choose to exclude other forms of information often discussed in evidence use literature, such as data. The field of data driven decision making has a number of established frameworks from which researchers and practitioners can draw when designing inquiries (see Coburn and Turner, 2011; Marsh and Farrell, 2015). Yet there is no research use framework from which to do the same. There is a need for a conceptual framework on research use to structure studies in this area. Data use in school level decision making can be linked to research use. However, we chose to keep the categories separated to focus on research use in school level decision making.

We see research as a potentially central form of information that can contribute to decision making in schools. Research can inform or shape choices and actions among decision makers as decisions accrete over time. Indeed, studies of school leaders’ research use find that most claim to value and use research regularly (Levin, 2010; Saha, 2009), particularly when the research is perceived as relevant to their school (Vanderlinde and van Braak, 2010). In fact, some argue that research can be more relevant for decision making if educators are situated as knowledge creators and active partners in the research process, in addition to knowledge consumers (Hiebert et al., 2002; Stanovich and Stanovich, 2003; Vanderlinde and van Braak, 2010). Action research has, in particular, been positioned as a framework through which educators might approach systematic inquiry and reflective practice

(Cochran-Smith and Lytle, 1990, 2009; Hiebert et al., 2002). More recently, frameworks like design-based methods and improvement science have been forwarded as tools for guiding practitioners' efforts to engage in systematic inquiry (Anderson and Shattuck, 2012; Bryk, 2015; Cohen-Vogel et al., 2015).

In Fig. 1, we represent the role of research in decision making with an "R." At some points of deliberation, research may enter the conversation. The introduction of research may, but does not always, happen in a predictable way. When decisions are made to select, (re)design, or maintain educational policies and practices in schools, the process is most often a social, irregular one that occurs over a period of time as individuals deliberate in varied groupings.

Studies have found multiple factors that mediate research use in daily school level decision making. To begin, school leaders and teachers often lack easy access to research, as well as the time and support needed to read and reflect on the pertinence of the research for their schools (Hemsley-Brown and Oplatka, 2005; Sheard and Sharples, 2016; Williams and Coles, 2007). Further, while some leaders do have access to research through journals and books, they also rely on secondary sources such as colleagues and professional meetings to highlight worthwhile research (Biddle and Saha, 2006; Levin, 2010). Indeed, many school leaders report personal experience and the input of colleagues to be more powerful influences on their beliefs than research (Levin et al., 2011). Additionally, school leaders and teachers stated the nature and format of research can effect its use, such as its communication quality and its timeliness (Cousins and Leithwood, 1993; Levin et al., 2011; West and Rhoton, 1994). For instance, in Vanderlinde and van Braak's study (2010, p. 306), principals shared that "... many researchers speak and write in a language that is unintelligible to practitioners", and that the use of such technical language may impede principals' efforts to use research. Moreover, as shared above, educators' perception of the validity of research and its relevance to their professional practice mediate their use of research in their decision making (Bickel and Hattrup, 1995; Boardman et al., 2005; Cochran-Smith and Lytle, 1990; Cousins and Leithwood, 1993; Levin et al., 2011; West and Rhoton, 1994). These findings indicate that leaders prefer research with clear, practical suggestions about what works (Vanderlinde and van Braak, 2010). To add to this, Coburn and Talbert (2006) find that principals are more likely than teachers and central office leaders to be skeptical of the value of research, and to prefer multiple forms of evidence. The authors surmise that principals' responsibilities "place demands on them to bring coherence among multiple kinds of validity standards represented in various assessments and data" (Coburn and Talbert, 2006, p. 485).

Additionally, a few studies point to organizational characteristics that also mediate research use in decision making (Cousins and Leithwood, 1993; Levin et al., 2011; Sheard and Sharples, 2016). For instance, Cousins and Leithwood (1993) find that an organization's information needs, focus for improvement, political climate, and competing information shaped whether and how school leaders used research. Research is also more likely to be used when organizational structures, processes, and culture support it (Levin et al., 2011; Sharp et al., 2006), such as when school leaders are explicitly guided on how to apply research, or when they have knowledgeable mentors who help create research engaged environments. However, as we discuss next, research use is likely shaped by other organizational factors not yet examined in this literature.

School level factors that shape research use in decision making

Building on the limited existing literature on how organizational context shapes the use of research in school level decision making, we synthesize existing organizational literature to highlight several important factors that likely shape school level decisions. We understand schools to be complex social organizations. The core activities in a school are managed by both formal and informal leaders (Spillane and Zuberi, 2009; Sun et al., 2013) who jointly select, (re)design, and maintain a school's policies, internal structure, culture, and routines (Scherer and Spillane, 2011). Here, we focus on three organizational factors that shape that process—(1) authority, (2) status, and, (3) organizational routines.

Formal and informal authority

Decision making, and the role of research and other information therein, is influenced by formal and informal authority relations. For instance, school leaders and teachers with authority can intentionally or unintentionally shape the decision making process (Wong, 2019). This includes bringing information such as research to the decision making process and influencing how their colleagues use that information during their deliberations (Coburn, 2005).

Formal authority is power "coded into structural design" (McAdam and Scott, 2005, p. 10) as comes with hired positions. We often think of formal authority at the school level belonging to principals. Indeed, studies exploring research use at schools often reference this authoritative position. Levin (2010) review of the literature, for instance, found that across studies, school level research use was influenced by social setting, and, in his account, principals were a key influence on that setting. Sharp et al. (2006) also found that school staff recognized when their leaders valued and held knowledge about research, suggesting that leaders' knowledge may be a strong predictor of research use throughout the school. In a mixed method study of principals in Australia and the United States, Saha (2009) found that principals passed on their own research literacy skills to teachers at their schools. Another way to state this could be that school staff are exposed to research through their principals' knowledge—or lack thereof—emphasizing the importance of this formal position. One could imagine a principal being a gatekeeper, bringing research into the organization and influencing staff's exposure, and an agenda setter, calling for particular research use in meetings

or professional learning opportunities. In this way, the principal can influence the flow of research into the school as well as its use within the school. At the same time, they may also serve as a limiting factor, choosing only research that fits with their individual preferences.

However, administrators are not the only actors to exert influence on schools' decision making processes. Any effort to understand school level decision making must go beyond the principal to explore the role of informal leaders in the process. These individuals may have informal authority, or authority ascribed to an actor related to characteristics other than their officially recognized position (Scott and Davis, 2007). Informal authority belongs to those who actually take responsibility in practice, which may deviate from official arrangements. Individuals who have no formal leadership designation, but may have informal authority, may influence the role of research in decision making. While this has not yet, to our knowledge, been studied in relationship to research use at schools, we know that informal authority does carry influence in schools. Evidence suggests that instructional decision making at the school level, in fact, involves an array of actors (Gronn, 2003; Leithwood, 2007), indicating the need to look beyond formal authority as an influence in decision making and research use.

Status

Similarly, people with higher status in a group might find their perspectives privileged during decision making, creating imbalances in interpretive contexts (Coburn et al., 2008) and allowing them to hold sway in negotiations (Camburn et al., 2003; Leithwood and Mascall, 2008; Spillane et al., 2007). Educators with less experience, for instance, may defer to the judgment of their more experienced colleagues on how to use and interpret research. Status refers to power associated with "unobserved performance expectations" (Balkwell, 1994, p. 124) that often result in prestige and may influence interactions within groups. Status is typically negotiated in a social situation, and can be rooted in fundamental characteristics (i.e., race, gender, or age) or achieved ones (i.e., academic background or occupational history) (Coburn et al., 2008; Dornbusch and Scott, 1975). Though not explicit, there are echoes of status in existing school research use literature. In a study by Sheard and Sharples (2016), the authors partnered with three English primary schools on a process of research engagement. Among other factors, they found that "recognition of professional experience and expertise" (p. 682) among the involved school actors contributed to a climate more supportive of in-depth research use. In this example, status led to a culture more conducive to research use. One could imagine status working in other ways; an individual with a prestigious background, for instance, could influence which, when, and how research gets interpreted.

Organizational routines

Organizational routines are another school level factor that shapes decision making. Organizational routines are "repetitive, recognizable pattern[s] of interdependent actions, involving multiple actors" (Feldman and Pentland, 2003, p. 95). In schools, routines related to decision making might include such activities as school improvement planning, designing and facilitating professional development, leadership team meetings, or instructional rounds, among countless others. These routines are both mediums for and outcomes of decision making; they can emerge from everyday practice or can be intentionally designed by school and district decision makers (Cohen and Bacdayan, 1994; Pentland and Feldman, 2008). Some routines are developed at the school site, while others are district mandated.

Organizational routines are organizational structures that shape who collaborates with whom about what, determining which individuals participate in decision making and what research and other information can be brought to the table during a discussion. Investigations into school level research use commonly—though not always overtly—demonstrate that organizational structure has the potential to improve school actors' use of research (Datnow and Park, 2010; Sharp et al., 2006; Sheard and Sharples, 2016). According to Levin (2010, p. 312), leaders who want to build a culture of research use at their schools should consider organizational structure: "The very fact that research findings and implications have a place on the agendas of staff meetings or principal meetings changes the way people in the organization think about research and, if done in ways respectful of professional responsibility, is likely to increase receptivity." Yet, studies have not investigated research use explicitly in light of routines. To understand research's role in schools, it is important to pay attention to routines as they relate to decision making practices.

District-school arrangements that shape school level decision making

Schools are components of broader school systems, and system leaders can influence school leaders' and teachers' practice, including influencing the use of research in school level decision making.¹ School level decision making is a phenomenon that can include stakeholders and activities across the school system, involving people and policies from district central offices, other schools, community members, Board members, and other organizations and stakeholders. Here, we focus on how district-school arrangements can shape research use in school level decision making. District central offices can exert varying degrees of control over

¹The relationship between schools and districts has bidirectional influence (Honig and Venkateswaran, 2012). However, since our focus is on school level decision making, we do not specify in this framework ways that schools may influence districts.

the decisions that schools have a say in, the research that school leaders have access to, how school leaders interpret and utilize research, and the viable options school leaders can consider (Honig and Venkateswaran, 2012; Ikemoto and Marsh, 2007). Thus, we highlight three district-school arrangements—(1) jurisdiction, (2) routines, and (3) informal social networks—to understand how these arrangements can shape the role of research in school level decision making.

Jurisdiction

Districts differ in the domains over which central office administrators have authority, and which aspects are controlled by school administrators. That is, districts vary in patterns of jurisdiction; in one, schools may be responsible for the majority of their instructional decisions, while in another, the central office makes the preponderance of calls related to instruction. Jurisdiction over decision making may also vary within school districts, where different schools may be given varying levels of autonomy. For example, some districts grant school leaders more or less autonomy based on student achievement scores.

Jurisdiction may be formal or informal. For instance, while a district may officially have authority over one aspect of instruction, schools may informally make decisions about it themselves. We also found the opposite in a recent analysis (Wong et al., 2020). Even though school leaders in two site-based decision making districts had formal jurisdiction over most aspects of instruction, their central office leaders' successfully used persuasive strategies to encourage them to make decisions in line with central office preferences. Further, there may be ambiguity with respect to which level has jurisdiction over a given issue. In some districts, the central office might be responsible for selecting research, compiling summaries, and facilitating meetings in which research is discussed (Levin et al., 2011). Schools in such districts would potentially gain access to research that they may not otherwise have had, but the district would in this case be responsible for narrowing the content to which school actors were exposed. This stands in contrast to schools where professional development is almost exclusively managed at the school site. Jurisdiction may also be influential in less direct ways—for instance, who has the final word about curriculum selection, or who designs discipline policies, both cases in which research may arise.

District-school organizational routines

Similar to school level organizational routines, district-school organizational routines are opportunities for central office and school leaders to collaborate and share information such as research. District-school organizational routines influence which central office and school staff are involved in discussions, what research and other information are used, and in what ways (Coburn and Turner, 2011; Little, 2012). For instance, in districts where central office leaders do have jurisdiction over professional development, the planning and delivery of the training are examples of routines that connect the school with the district central office. If individuals from both of those levels work with one another at different steps of the process, there is further opportunity for access and exposure to research. Of course, training is only one illustration of a routine connecting the school and district. Other examples of connecting routines include teacher evaluation processes, district walkthroughs, cross-district meetings for teacher leaders or school based coaches, or principal professional development sessions.

District-school informal social networks

District-school connections may also occur through informal social networks, opportunities for central office and school leaders to reach out to each other as needed. For example, school leaders may reach out to central office leaders for advice on a decision (Wong et al., 2020). The research and other information central office leaders offer can then shape school level decision making processes. Ties that span boundaries allow for new information to enter each organization and minimize "groupthink" among organizational members (Burt, 2000; Hansen, 1999; Krackhardt and Stern, 1988). The greater the trust built within these networks, the more willing participants may be to share and exchange information in situations that require them to be vulnerable and take risks. When connections between central office and schools are weak, they tend to handicap schools' use of research (Daly and Finnigan, 2010). The nature of information passed through a network, and the likelihood that it will influence decision making at the school level, may depend upon the structure of social networks beyond the formal connections already discussed here. School actors may be exposed to research through a friend or past colleague, or a district actor with whom they share an informal association.

Animating our conceptual framework

In this section, we bring together the key concepts from our framework to illustrate how they collectively and dynamically interact as dimensions of the decision making process. Our conceptual framework utilizes an organizational lens to provide a contextualized approach for understanding research use in schools—an approach that we currently use in our own studies. We provide an extended example to illustrate how these organizational dimensions of schools and school systems interact to influence the role that research plays in school level decision making. While the anecdote is hypothetical, it is rooted in composite experiences our team has observed throughout various studies, combined to illustrate the application of this conceptual framework.

Consider this scenario: an elementary school leadership team must decide what math curriculum they should adopt in the upcoming school year. They have a number of options on the table and, given that this is a potentially expensive and impactful

decision, the topic is introduced and reintroduced in full staff meetings, at math department meetings, and in schoolwide leadership meetings. This curricular decision is also discussed during informal conversations. During some of these deliberations, research is introduced. At one point, the math department chair introduces research that she was given during an evening graduate level class, which appears to support one program over the others. A third grade teacher searches online for expert reviews on the potential options available, then mentions them to colleagues over lunch. Over the course of months, the conversation begins to take shape around a particular set of ideas, some informed by research. This seemingly messy process exists, in our diagram, in the dashed box in the upper right corner.

The process is influenced by a number of factors within the organization. These elements in our diagram are present at the school level—the larger box on the right. Formal and informal authority, status, and organizational routines each have the potential to influence the role research plays in these processes. For instance, in our hypothetical example, authority may determine to some degree which research is introduced into deliberations about mathematics curriculum. The principal, for instance, may include time on a staff meeting agenda to discuss opinions about new math curriculum, including the introduction of an article she believes to be relevant. Given her position as principal, one which is imbued with formal authority, the research she introduces is not questioned publicly, though a number of teachers may find flaws with its premise. Perhaps while discussing this particular piece of research in the staff meeting, the principal's interpretation of how its findings apply to their selection of curriculum is either the only interpretation discussed, or the one given the most attention. In these ways and myriad others, an individual in a position of authority may influence which research reaches deliberations, and how it is interpreted.

Other organizational factors—such as status and organizational routines—also play a role in how research may be used at the school level. For instance, in our hypothetical example, a teacher with a graduate degree may leverage her status to challenge the principal's interpretation of research, publicly or in private. Further, the principal's inclusion of research on the staff meeting agenda is one instantiation of how research use may be supported through the employment of organizational routines. But, as the organization is porous and influenced by elements outside its own boundaries, the school's use of research in decision making is also permeable, meaning that research can enter through other means.

Our conceptual framework focuses on three particularly generative ways in which research use may be influenced. These are arrangements between the school and the central district office: jurisdiction, district-school organizational routines, and district-school informal social networks. Jurisdiction influences research use at a number of points in our hypothetical example of school level decision making. If the school district, for instance, mandated a particular mathematics curriculum, the question of selection would be moot. Research regarding mathematics curricula may not be pulled into the school's decision making arena at all, in this case. In addition, it is possible that the district office could mandate a particular professional development series, therefore limiting the degree to which the principal could introduce her own selection of research to the staff at large. Organizational routines that connect the school and district, such as the planning and implementation of professional development, might favor a different set of research, based on the training and preferences of the district level team involved. Finally, informal social networks that connect school level actors with those in the district serve as another channel for research—and interpretations of research—to enter the deliberative field. These social networks are again a means for sharing information that may influence the types of research on the table and how they are leveraged in discussions. Again, the examples provided above are compiled from a variety of research experiences and are selected for illustrative purposes. It is not often that such clean cut instances of research use arise in reality. Although we focus in this article on the school level, the bidirectional arrows between the school and the district serve as recognition that interactions with the school can influence district level deliberations, as well.

Conclusion

To the conversation on research use in schools, we offer a view of decision making that is social and additive, an organizational lens, and most tangibly a framework through which to further explore this pressing topic. Our team is currently using this conceptual framework in a multi-city, multi-year study of research use in districts and schools. Though we anticipate new and improved iterations will follow in future investigations—ours as well as others'—our hope is to set the stage for deeper explorations of research use at the school level, remaining cognizant to factors that influence the processes of decision making in which research plays a role.

Our framework opens up school level decision making to include the impact that organizational context can have on whether and how educators use research within their decision making. District-school and school level organizational routines, informal social connections, jurisdiction, status, and authority all mediate whether educators learn about research and how, if at all, they use the research in their decision making. In addition to individual and access factors, we can examine these organizational factors to understand and better support research use in schools. Viewing research use through an organizational lens helps us situate and contextualize whether and how research is used in instructional decision making.

This organizational framework is a critical addition to the existing conversation on research use in schools, and a useful one for pressing forward in our understanding of school level decision making and the role of research therein. To separate the decision making process from school and district organizational influences misses elemental components of the story. In presenting this framework, we make the argument that consideration of organizational factors should not be incidental to any study of decision making, but should instead play a central, framing role from the inception of the investigation.

Further studies are necessary as current policies continue to press educational practitioners toward evidence-based decision making. We argue that the school level is becoming increasingly important in this conversation, as policy changes—such as the

Every Student Succeeds Act in the US—signal a move to more on-the-ground autonomy in instructional choices. If this policy is taken as an indicator, we are entering an era in which school level decision making will be increasingly taking center stage. We end with a call to our research colleagues to usher it in with the goal of understanding how organizational dimensions play a role in this important process.

Principal leadership has consistently been regarded as a critical factor in influencing student learning and school improvement (Grissom et al., 2021; Hallinger et al., 1996; Hallinger and Heck, 1996b, 1998; Leithwood et al., 2004; Witziers et al., 2003). A review of research on leadership published by the Wallace Foundation in 2004 (Leithwood et al., 2004), claimed that “Leadership is second only to classroom instruction among all school-related factors that contribute to what students learn at school” (p. 5). A subsequent publication by the same research team (see Louis et al., 2010) strengthened this claim, noting that “After six additional years of research, we are even more confident about this claim. To date we have not found a single case of a school improving its student achievement record in the absence of talented leadership” (p. 9). A more recent study commissioned by the Wallace foundation and authored by Grissom et al. (2021), noted that “Effective principals are at least as important for student achievement as previous reports have concluded—and in fact, their importance may not have been stated strongly enough” (p. xviii). This review further noted that “it is difficult to envision an investment with a higher ceiling on its potential return than a successful effort to improve principal leadership” (p. xiv).

The initial Wallace report that reviewed prior leadership studies noted that leadership had small but statistically significant effects on student outcomes. Other reviews of school leadership studies have reached similar conclusions (see for example, Hallinger, 2005; Hallinger and Heck, 1998; Liebowitz and Porter, 2019; Neumerski, 2012). Hallinger (2005) notes that “The preponderance of evidence indicates that school principals contribute to school effectiveness and student achievement indirectly through actions they take to influence school and classroom conditions.” (p. 9), and that “The size of the effects that principals indirectly contribute toward student learning, though statistically significant, is also quite small.” (p. 9). More recently, Tan et al. (2020) conducted a second-order meta-analysis of primary studies that spanned four decades of research and found small overall mean effects size for school leadership. The description of leadership effects as small is based on Cohen’s criteria by which an effect size of 0.20 is characterized as small, 0.50 as medium, and 0.80 as large (Cohen, 1962). A different way to interpret these effects is to compare them with other organizational factors or educational interventions. Grissom et al. (2021) for example, compared leadership effects with teacher impacts and found that “the impact of having an effective principal on student achievement is nearly as large as the effect of having a similarly effective teacher” (p. xiii).

Besides the finding that leadership effects can be characterized as small (according to Cohen’s criteria), there is also consistent evidence that these effects mostly occur indirectly (Neumerski, 2012), through mediating processes such as goal setting and maintaining or changing the school’s mission and vision (Hallinger et al., 1996; Leithwood and Jantzi, 2008; Louis et al., 2010; Supovitz et al., 2010), teacher development and support (Leithwood, 1994; Marfan and Pascual, 2018; Shen et al., 2016), organizational management (Leithwood and Jantzi, 2008), instructional and program coherence (Sebastian and Allensworth, 2012), parental involvement (Sebastian et al., 2016; Shen et al., 2016), and school climate (Dutta and Sahney, 2016; Sebastian et al., 2014, 2017). Hallinger and Heck (1998) note that “we conclude that convincing empirical evidence suggests that principals do affect school outcomes. The impact is, however, achieved primarily through complex indirect relationships with other external environmental forces (e.g., community) and in-school processes” (p. 185). It is important to note here that a few studies have argued that leadership can also have direct effects (Hallinger and Heck, 1998; Silva et al., 2011; Wu, 2020; Wu et al., 2020).

Researchers interested in studying indirect effects of school leadership typically use Structural Equation Modeling (SEM) to examine the role of specific organizational features in mediating leadership effects (see for example, Hallinger and Heck, 1996a,b, 2010a; Heck and Hallinger, 2009; Sebastian and Allensworth, 2012; Sebastian et al., 2016, 2017). Researchers have examined a wide array of mediational factors to understand school leadership effects, depending on their conceptualizations of leadership and theoretical perspectives about school organization. For example, Leithwood et al. (2010) and (2020) classified four unique paths through which principals influence learning: (a) rational path, that includes foundational aspects of schooling such as instruction and classroom practice, academic press, and disciplinary climate; (b) emotional path, which contains job satisfaction, teacher

academic optimism and expectation, trust, teacher collaboration, and teacher self and collective efficacy; (c) organizational path, which includes safe and orderly environment, school organization aspects, and capacity for school improvement, and (d) family path, which includes variables such as parent and parent involvement. Wu (2020) used Leithwood's criteria to review leadership studies that have used the indirect-effects approach and noted that the most commonly examined set of organizational variables in mediational studies were classroom instruction, teacher collective efficacy, professional learning community, and school climate.

So far, in prior school leadership research, there is little discussion about which component of leadership mediational pathways results in overall small effects from leadership to student outcomes. In general, if we consider any path from school leadership (X) to learning (Y) via an organizational mediating process (M), the total indirect effect (X-M-Y), involves two components, school leadership to the mediator (X-M), and then mediator to outcome (M-Y). It is important to examine these two components to understand where mediational pathways are diminished. For example, the finding that a specific leadership pathway to any school outcome (e.g., teaching/learning) is not statistically significant, could be due to X-M or M-Y, or both. Similarly, if an overall indirect pathway via a specific mediator is significant but small, it could be that X-M is small, but M-Y is large, or vice-versa. Alternately, all components of the mediational pathway could be small. In the present chapter, we review evidence from a large urban school district—Chicago Public Schools (CPS), using longitudinal data and an array of organizational mediators to disentangle the relationships between school leadership, organizational processes, classroom instruction, and student learning outcomes. In the following sections, we first summarize the Essential Supports framework that we use as the conceptual basis for the study, we next review the main findings from a series of school leadership studies conducted using CPS data, and then examine specific components of the mediational pathways examined in these studies.

Essential supports theoretical framework

As noted earlier, school leadership researchers have examined a wide array of school organizational factors depending on their theoretical frameworks and definitions of leadership. Hitt and Tucker (2016) conducted a review of school leadership studies and highlighted three leadership frameworks as noteworthy—the Ontario Leadership Framework (OLF), Learning-Centered Leadership Framework (LCL), and the Essential Supports Framework. These were identified as influential frameworks that described effective leadership practices and had strong empirical support. The Essential supports framework is of relevant here because the CPS leadership studies reviewed in the present study used this specific framework to examine mediational leadership relationships.

The Essential Supports Framework proposes a multiple-mediational pathway that begins with school leadership and works through organizational processes of parent-community ties, staff professional capacity, student-centered learning environment, and ambitious instruction (Bryk et al., 2010; Sebring et al., 2006).

Based on longitudinal studies of elementary schools in Chicago, spanning from 1990 to 2005, Bryk et al. (2010) showed that schools that were strong on multiple dimensions of the five essentials framework were about 10 times more likely to improve during a period of education reform than schools that were weak on multiple dimensions. The focus of leadership in this framework is principal instructional leadership, but it also recognizes the importance of distributing leadership throughout the school, as evidenced by the involvement of teachers in school policy and work. As shown in Fig. 1, in this model, leadership works indirectly through multiple mediational processes to improve classroom instruction and student learning. The framework highlights how the main school organizational factors that influence student achievement are interconnected, and proposes that without a strong leader, school reform efforts are significantly less likely to be successful (Bryk et al., 2010).

School leadership studies in Chicago Public Schools (CPS)

In a series of studies funded through a research grant from the Institute of Education Sciences (IES) Department of Education, the University of Chicago Consortium on School Research utilized personnel survey data and student achievement data from CPS to study school organizational factors through which school leaders influence student learning. The results of these studies have been published (see Allensworth and Hart, 2018; Allensworth et al., 2020; Sebastian and Allensworth, 2012, 2013, 2019; Sebastian et al., 2016, 2014, 2019, 2017; Wiedermann and Sebastian, 2020a,b). The survey instruments for these studies were developed by the Chicago Consortium based on the Essential Supports framework. The Chicago Consortium collects longitudinal data on different aspects of the five essentials framework (including leadership, organizational factors, teaching, and learning), keeps rigorous documentation of instrument development and data collection, uses consistent survey items, and follows Rasch modeling for measure development. This allows for longitudinal modeling and analyses and valid comparisons across years (Bryk et al., 2010; Luppescu and Ehrlich, 2012; Sebring et al., 2006).

The Chicago Consortium leadership studies used Structural Equation Modeling (SEM) to link survey data on leadership and organizational processes with CPS administrative data on student test scores and grades. The longitudinal design of the studies allowed for studying the relationship of school leadership with improvement in student learning over time. Further, these studies controlled for student demographic and school contextual characteristics and examined elementary and secondary levels separately. A criticism of the SEM approach is that it evaluates pathways net of each other (Fiss, 2007, 2011; Ragin, 2008; Ragin and Fiss, 2008). For example, using SEM to study leadership allows us to evaluate the importance of professional development as a mediator, net of all other mediators. However, in actual practice, school leaders work on multiple organizational factors together and their

Fig. 1 Adaptation of the five essentials framework to examine mediational leadership pathways. Adapted from Bryk, A.S., Sebring, P.B., Allensworth, E., Luppescu, S., Easton, J.Q., 2010. *Organizing Schools for Improvement Lessons From Chicago*. University of Chicago Press.

combined work on two or more mediators could result in improvements to student learning. In order to examine combinatory effects of multiple mediators acting together, the Chicago Consortium leadership studies also used a method called Qualitative Comparative Analysis (QCA) that helps to uncover combinatory patterns of the five essential supports as they relate to student outcomes (see Sebastian et al., 2014). As part of the IES grant, qualitative studies also sought to examine what differentiated the work of strong school leaders that ultimately translated into improvements in student learning. This was conducted using case studies of principals and teachers in schools which reported having a strong school principal but showed variation in their student achievement gains (see Allensworth et al., 2020). In the present manuscript, we will focus only on the quantitative studies to examine specific components of SEM models more closely.

Results of the Chicago Consortium leadership studies

The main results of the CPS leadership studies have been reported in refereed journal articles (see above). In brief, we found across multiple studies, examining elementary and secondary schools, and using cross-sectional and longitudinal data, that only the leadership pathway via school learning climate was statistically significant. We conceptualized school learning climate as an environment fostering high academic expectations and a safe and orderly climate. Our mediational studies found that none of the other pathways were statistically significant, net of learning climate. The remaining direct path between leadership and student learning was also not statistically significant. Further, the estimate of the only significant indirect pathway linking leadership to student learning (via learning climate) could be classified as small according to Cohen's criteria. Fig. 2 shows one example of the results and describes mediational pathways from high school data; these results were consistent across the other SEM studies using the Chicago Consortium data. Our results are also consistent with previous leadership mediational studies that found that the relationship of school leadership with student learning is largely indirect and overall effects tend to be small. However, prior studies typically had often included only one mediator in their analysis (see for example, Dumay et al., 2013; May and Supovitz, 2011). Other studies combined multiple school organizational factors into one overall global factor such as school capacity (Hallinger and Heck, 2010a,b; Heck and Hallinger, 2009). The CPS studies utilized the Essential Supports framework to examine multiple school mediators simultaneously. This approach helped in identifying which organizational processes school leaders could prioritize in their efforts to improve student learning.

The Consortium studies that examined the relationship of combinations of multiple organizational processes, including school leadership, also highlighted school learning climate as the most important component (Sebastian et al., 2014). In sum, across all our studies, we found that the strongest and only significant link between leadership and teaching/learning was via school climate, and that school climate mattered in all contexts. Even in schools that already had a strong school climate, improvements in school climate translated to further student achievement gains (Sebastian and Allensworth, 2019). We interpreted these findings in the following way:

Because all classrooms are affected by school climate, a principal's influence on climate may have the broadest reach across all the different classes in a school. As the school leader, the principal manages the work environment for everyone in the school. The more that students, teachers, and staff feel

Fig. 2 Direct and indirect pathways from principal leadership to student achievement and student achievement gains. Adapted from Sebastian, J., Huang, H., Allensworth, E., 2017. Examining integrated leadership systems in high schools: connecting principal and teacher leadership to organizational processes and student outcomes. *Sch. Effect. Sch. Improv.* 28(3), 463–488.

safe and hold high expectations, the easier for everyone to be successful at teaching and learning. Efforts by principals to improve a school's climate do not require subject-specific knowledge or skills. While school leaders may not have content knowledge or expertise to be proficient in every subject, they can indirectly promote good instructional practices by creating a supportive school climate. This has some implications for how school leaders should organize their daily work. If school climate is the primary mechanism through which principals can influence classroom instruction and student learning, then principals need to prioritize climate in school improvement efforts (p. 9).

Disentangling pathways from leadership to student learning

In our previous CPS leadership studies, we reported the direct and indirect pathways from the SEM models, their coefficients, and standard errors. However, our discussion of results emphasized only the overall statistical significance of indirect pathways. In the present chapter, we consider the SEM results in closer light, to re-examine different sections of each leadership pathway.

Across all the Consortium leadership studies that used SEM models, the relationships between measures of leadership and all measures of mediating organizational processes were statistically significant. Fig. 2 shows that all paths from leadership to mediators (X-M)—parent/community ties, program quality, professional development, and learning climate were statistically significant. Using Cohen's criteria, the path estimates from leadership to professional learning community and professional development were moderate, whereas the path estimates for parent ties and learning climate could be classified as small. However, when examining the next stage of each mediational pathway, from the mediators to classroom instruction (M-Y), none of the relationships were statistically significant except for learning climate. Therefore, for most mediators, it is the second stage of leadership pathways that results in overall non-significant indirect effects. When considering the pathway via learning climate, net of the other, which is the only significant mediator, the path estimate for the first stage—leadership to climate (X-M), is weaker than the second stage (M-Y). For every other pathway, the correlation between leadership and the mediator (X-M) is stronger than the correlation between that mediator and the outcome (M-Y).

Taken together, these results show that for all school organizational processes that school leadership is theoretically expected to impact, empirical evidence suggests that leadership is indeed significantly related to those processes. When teachers in CPS reported higher levels of instructional leadership, they also reported higher levels of program quality, professional community, teacher professional development, parent/community involvement, higher academic expectations for students, and higher perceptions of safety. One limitation in using survey data is the potential for subjective bias that could arise from single-source survey reporting (Camburn et al., 2017). However, we utilized student, teacher, and principal survey reports for informing different measures used in the SEM models, and except for learning climate, the same patterns were consistently observed—strong correlations from leadership to mediating factors and non-significant relationship from the mediator to the outcome, except for learning climate.

Discussion and implications

The results of the present study show that when examining the second stage of leadership pathways to school outcomes (M-Y) using CPS data, we observe that in most cases relationships are not statistically significant. Although theory proposes that different school organizational processes should relate to the quality of classroom instruction and student learning, empirical evidence in the CPS

Table 1 Variables descriptive statistics.

<i>Name</i>	<i>Mean</i>	<i>SD</i>
Principal leadership	−0.02	0.60
Professional learning community	−0.01	0.68
Professional development	−0.02	0.47
Learning climate	0.03	1.49

Adapted from Sebastian, J., Huang, H., Allensworth, E., 2017. Examining integrated leadership systems in high schools: connecting principal and teacher leadership to organizational processes and student outcomes. *Sch. Effect. Sch. Improv.* 28(3), 463–488.

context does not bear this out. This could be due to the unique context from where the data was collected, a large urban district where school learning climate is particularly important. Another reason could be that differences between schools on several mediators (organizational processes) are not large when compared to differences in school learning climate (see [Table 1](#)), or that those differences do not relate to school-level differences in classroom instruction and student learning, net of school climate.

Comparing our results to other mediational studies that have examined leadership pathways to student outcomes, many of them show results that are consistent with what we described here—stronger relationships from leadership to mediators and weaker (and often non-significant) relationships from the mediator to student learning. [Leithwood et al. \(2020\)](#) examined the links between leadership and student learning via four mediational paths—rational, emotional, organizational, and family; for all these paths, the path estimates from the leadership measure to each mediator was stronger than the corresponding path from that mediator to student learning. Similarly, other leadership studies (see for example, [Dumay et al., 2013](#); [Supovitz et al., 2010](#)) also show that links from leadership to various mediational factors are relatively stronger than the corresponding relationships between mediators and student outcomes.

[Wu \(2020\)](#) recently reviewed leadership studies that have utilized SEM models to examine direct and indirect pathways to student outcomes. [Wu \(2020\)](#) classified these studies based on [Leithwood et al. \(2010\)](#) and (2020)'s four-path model including rational, emotional, organizational, and family paths as mediators. We examined the mediational studies reviewed by [Wu \(2020\)](#) and examined specific components of mediational pathways from leadership (X) to student outcome (Y) via mediating processes (M). As shown in [Appendix A](#), we cataloged 95 mediational pathways from X to Y (via M) in 36 articles. Among 95 X-M-Y pathways, there were 62 cases in which X-M had a larger effect size than M-Y, 28 cases in which X-M had a smaller effect size than M-Y, and 5 cases for which estimates for specific pathway sections were not available. As with the Consortium IES leadership studies, for most pathways, the specific component of most leadership pathways where the overall indirect effect becomes non-significant or small (according to Cohen's criteria), is the section from the mediator to the outcome (M-Y) and not leadership to mediator (X-M). Taken together, these results can help the field clarify the reasons overall leadership effects are small. The weak indirect leadership effects are not due to weak links from leadership to organizational processes that leadership is expected to influence. Instead, the weak effects arise from weak correlations between school organizational processes and student outcomes.

The CPS studies show that leadership has an influence on all organizational processes that it is theoretically expected to influence. However, the links between these organizational processes and teaching/learning are not significant. As noted earlier, one of the reasons for this could be that school-level variation among organizational mediating factors is highest for learning climate (see [Table 1](#)). Therefore, schools vary widely in their learning climates and are relatively more similar on parent/community ties, professional development, and professional learning communities. This could be unique to urban school contexts such as CPS; however, the importance of learning climate has been emphasized in other studies using more generalizable data (see for example, [Leithwood and Sun, 2018](#); [Leithwood et al., 2020](#); [OECD, 2010, 2016](#)). [Leithwood and Sun \(2018\)](#) showed that academic culture—a latent variable comprised of academic press, disciplinary culture, and teachers' use of instructional time, significantly mediated the relationship between school leadership and student achievement. It is noteworthy that their academic culture construct is conceptually similar to the learning climate construct used in the CPS studies. [Leithwood et al. \(2020\)](#) compared multiple mediational pathways using the four-paths model and found that only the rational path mediated the relationship between leadership and achievement, again emphasizing the importance of academic culture.

Another reason could be the net-effects approach used in SEM studies, where each mediational pathway is evaluated net of other pathways ([Ragin and Fiss, 2008](#)). Our QCA study ([Sebastian et al., 2014](#)) sought to examine configurations of multiple organizational processes in relation to student outcomes. However, here again, the organizational process that was shown to be critical to effective school leadership was school learning climate alone. The use of QCA is only one method that has been proposed to examine the importance of multiple configurations and some critiques of the method have been noted (see for example, [Achen, 2005](#); [Seawright, 2005](#)). The research on examining combinations of multiple mediational pathways from leadership to student outcomes is still developing. Another possibility is a theoretical reconceptualization of school organization where school climate is seen as a primary mediator that in turn influences other organizational factors as secondary mediators. In the Consortium studies, if learning climate was not included in the SEM models, other mediators such as professional learning community were significant mediators of leadership and achievement ([Sebastian and Allensworth, 2012](#)). One possibility is that organizational factors could

matter to student outcomes to the extent that they influence school climate and instruction. [Leithwood et al. \(2020\)](#), whose work also emphasized the importance of “academic culture” (a construct similar to learning climate), similarly suggested the need for future research to examine the complex relationships among the mediators themselves, for e.g., other mediational pathways could influence achievement through the rational path.

Our results showed that learning climate has a strong correlation with classroom instruction and student learning, whereas the links between leadership and learning climate can be classified as small. These results could be influenced by how teachers rate principals. Specifically, the measure of principal leadership may have functioned as a proxy for principals’ strengths in other aspects of leadership including organizational management skills ([Sebastian et al., 2016](#)). Our results also imply that there are many factors that affect a school’s learning climate other than the school leadership such as a school’s contextual and demographic characteristics. Taken together, principals provide an organizing framework to improve the overall climate of the school by supporting and guiding the work of school personnel ([Sebastian et al., 2017](#)).

Overall, our results provide a useful empirical basis for understanding principal leadership effects on student outcomes and considering new directions for research and practice. Principals strongly influence student learning to the degree to which a school is set up to support student learning. However, instruction and learning are influenced by factors other than leadership and school organization. Of all the organizational conditions studied here, school climate has the largest relationship to instruction. Whether professional development or trusting relationships with families leads to stronger instruction depends on what professional development is about, and how relationships are structured to support student achievement in school. More empirical research is needed to verify these results and more theoretical work is needed to consider the implications for school organization theory and leadership preparation. Based on these results, it does not appear that further emphasizing leadership skills in parent-community ties, professional development, and professional learning community, through professional training or through leadership preparation programs can have direct benefits for learning outcomes. This is because there is little correlation between those organizational factors themselves and student learning when we also consider learning climate in analytical models. An important caveat to this claim is that our evidence is only based on large-scale quantitative data sets. Further, they may be relevant for other outcomes and for the effective functioning of schools. For example, [Leithwood \(2021\)](#) reviewed prior research on leadership practices that improve equitable school outcomes and pointed to three sets of practices (see page 33): (i) creating “authentic partnership between schools, families, and communities”, (ii) reflecting the “ethnic, cultural, and linguistic assets that diverse students and their families bring to the school” (p. 33) in the school curriculum, and (iii) assisting teachers “with the implementation of ambitious forms of instruction for traditionally underserved student” (p. 33).

Finally, the relatively weak correlation between leadership and school climate shows that there is room for strengthening leadership skills in improving climate and that other factors besides leadership are relevant for influencing climate. Identifying those factors through reviews of prior research and more empirical organizational research that prioritizes learning climate appears to be key for school improvement efforts.

Schools are challenged to adapt to the needs of a rapidly changing world. Trust is a vital resource in times of crisis and change (Misra, 1996), thus school leaders would do well to invest in the cultivation of trust in their schools. Schools that foster high-trust environments are better positioned to accomplish the challenging task of educating a diverse group of students in a changing world.

What do school leaders need to know about trust?

It is imperative that school leaders are knowledgeable about and attend to issues of trust because trust is strongly associated with student outcomes in schools. A growing body of evidence attests to the powerful role that trust plays in student achievement (Adams, 2008; Forsyth et al., 2006; Goddard et al., 2001, 2009; Hoy, 2002; Hoy et al., 2006; Hoy and Tschannen-Moran, 1999; Tschannen-Moran, 2004). In a study of two districts, one urban and the other suburban, I found that 75% of the variance in student achievement was explained by a set of trust variables that included faculty trust in students, parents, colleagues, and principals, as well as student trust in teachers and parent trust in schools (Tschannen-Moran, 2014b). Moreover, in a decade-long study of Chicago public schools engaged in reform initiatives, Bryk and Schneider (2002) concluded that trust was a critical factor in predicting which schools would make the greatest gains in student achievement and which would sustain those gains over time. Further, comparative international research across seven countries demonstrated the key role that trust plays in student outcomes within these national systems of schooling (Fink, 2016). In the past five decades, educational researchers have searched diligently and largely in vain to identify variables that explain student achievement above and beyond the effects of SES. Trust, and specifically the reciprocal trust between teachers and students, has proven to be just such a powerful variable (Goddard et al., 2001, 2009; Hoy, 2002; Hoy et al., 2006).

Trust is essential for leaders in binding the hearts and minds of followers to a shared mission or goal. Faculty trust in the principal has been linked to student academic achievement in both direct and indirect ways (Chughtai and Buckley, 2009; Forsyth and Adams, 2014; Handford and Leithwood, 2013; Notman and Henry, 2011; Salfi, 2011; Tschannen-Moran, 2014b; Zeinabadi, 2014). Faculty trust in the principal has been related to both the collegial orientation of a principal's leadership as well as to instructional leadership (Tschannen-Moran and Gareis, 2015). To be productive and accomplish organizational goals, schools need cohesive and cooperative relationships, and trust is essential to fostering these relationships. Trust supports schools' effectiveness, improvement initiatives, and persistence in reform efforts (Bryk and Schneider, 2002; Cerna, 2014; Forsyth et al., 2011, 2006; Goddard et al., 2001; Louis, 2007; Tschannen-Moran, 2014a; Uline et al., 1998; Van Maele and Van Houtte, 2012). A culture of innovation and continuous learning, as well as the success of improvement initiatives, have all been tied to strong bonds of trust (Bryk and Schneider, 2002; Cerna, 2014; Cosner, 2009; Daly et al., 2014; Forsyth et al., 2011, 2006; Goddard et al., 2001; Hoy et al., 1996; Louis, 2007; Moolenaar et al., 2010).

Faculty trust has been related to the level and quality of collaboration in a school (Tschannen-Moran, 2001), teachers' perceptions of the professionalism of their colleagues (Tschannen-Moran, 2009), and the quality of professional learning communities (Hallam et al., 2014). When trust has been damaged or has failed to develop in the first place, teachers and staff members spend

their energy in hypervigilance, perennially on guard to protect themselves and their interests, which inevitably comes at the expense of collective goals. Students who do not trust their teachers or each other divert energy in self-protection and away from engagement with the learning task. Furthermore, students who do not feel trusted by their teachers and administrators may psychologically distance themselves from schools and build an alienated, rebellious youth culture that creates barriers to participation in the learning task. Students may, in fact, live down to the low expectations of a distrustful school environment. Moreover, the degree to which students trust their teachers has also been found to be strongly related to student achievement across a variety of contexts (Adams, 2010; Mitchell et al., 2008, 2018; Tschannen-Moran et al., 2013).

Because trust is so important to the productive functioning of schools, defining just what trust is and how it works in a school is important. The need for trust emerges in a situation of interdependence, in which valued outcomes cannot be achieved without the involvement and contribution of others (Tschannen-Moran, 2014a). A core aspect of trust is the deliberate acceptance of vulnerability at the hand of a trustee, despite the absence of guarantees that the other party will not violate that trust by acting opportunistically (Heyns and Rothmann, 2018). In schools, principals, teachers, staff, students, and parents are interdependent because none can accomplish the complex task of educating young people alone, but the shape and meaning of trust may differ based on the nature of that interdependence. Managing a diversity of trust relationships makes the work of educators particularly complex. Adding to the challenge of defining and studying trust is that fact that it is a complex and dynamic construct that can change over the course of a relationship, as the nature of the interdependence between parties changes and as expectations are either fulfilled or disappointed.

People make judgments as to whom to trust and to what extent based on several criteria or facets of trust. Much of the research on trust in schools has relied upon the following definition.

Trust is a feeling at ease in a situation of interdependence based on the confidence that the other person or group is benevolent, honest, open, reliable, and competent

Tschannen-Moran (2014a).

In the relationships between teachers and principals, this model in which the five facets form a unitary and coherent concept of trust has consistently held up when examined through exploratory and confirmatory factor analyses as well as qualitative investigations (Hoy, 2002; Hoy and Tschannen-Moran, 1999; Tschannen-Moran, 2014b). However, qualitative studies have also uncovered the potential for unevenness in trust relationships, based on differing expectations. For example, a teacher in an underperforming urban school reported that while he trusted his colleagues as friends, he did not trust them as professionals (Tschannen-Moran, 2014a). Thus, trust and distrust can both be present in a single relationship. Although various facets of trust may be salient, their relative weight will depend on the referent of trust (who is being trusted) and the nature of the interdependence between the parties. In a study of 205 schools (including survey responses from 205 principals and 1150 teachers) in Chile, Weinstein et al. (2020) found that in the relationships between teachers and their principal, benevolence was the facet of trust that carried the most weight in teachers' trust assessments. Furthermore, the facets most tied to character, that is benevolence, openness and honesty, as a group, carried more weight than those related to competence (i.e., competence and reliability). When principals were assessing their trust in teachers, however, the weightings were reversed. Reliability and competence played a stronger role, whereas those facets related to character were somewhat less potent.

To nurture high trust environments and to reap the benefits of trust, school leaders must earn the trust of their followers as well as cultivate a culture of trust throughout the organization. Although the constructs of trustworthiness and trust are related, Heyns and Rothmann (2018) highlight the distinction. While trustworthiness is a quality possessed by the person being trusted, trust itself is something that the trusting party does. A culture of trust is a set of tacit beliefs and assumptions that a group of people in an organization hold in common. Weinstein et al. (2020) observed that principals are the main drivers of a culture of trust in schools, setting the tone, as well as influencing the intensity and scope of the trust relationship in their school. In the sections that follow, we will discuss leadership behaviors associated with being trustworthy, as well as actions they can take to cultivate a high trust culture in their schools, exploring each of the five facets of trust in turn.

Benevolence

One of the most universally acknowledged foundations of trust is a sense of benevolence or positive regard expressed as a mutual spirit of good will and a willingness to extend oneself in support of the well-being of the other (Bryk and Schneider, 2002; Tschannen-Moran, 2014a). It is grounded in the confidence that one's well-being or something one cares about will be protected and not harmed by the person in whom they have placed their trust (Zand, 1997). Benevolence also entails a willingness to forgo personal gain if that gain would bring potential harm to the trusting party. The nature of benevolence may vary with the nature of the relationship. When there is a power differential in the relationship, as in the relationship between school leaders and teachers or between teachers and students, the person with greater power may characterize the sense of good will they are looking for in a subordinate as respect, whereas the person with less power in a relationship may characterize mutual good will as a sense of caring about one's wellbeing (Weinstein et al., 2020).

Conveying caring, empathy, and respect

For school leaders to be regarded as trustworthy, they must evidence an abiding sense of care for their constituents as persons, care for the relationship, and care for the shared project of schooling. Teachers expect principals to be aware of their particular situation, and to be concerned for their physical and psychological well-being. Teachers expect principals to play a role as protectors of their rights and to act as mediators between them and upper-level administrators to prevent teachers from being adversely affected by decisions made. Teachers trust in their principals grows when they note ways their principal takes initiative to improve the working conditions of teachers. Teachers expect the principal to view the staff not as mere workers but as real individuals with wants and needs. Benevolence involves having empathy for and being responsive to the needs of the other (Tschannen-Moran, 2014a). Weinstein et al. (2020) found that teachers were especially sensitive to the principals' knowledge about their specific health problems or major personal difficulties (for example, a relative passing away), and their willingness to be flexible regarding their duties while they were working through their personal difficulty. In a study of 116 schools in the United States, principal trust was directly related to teachers' perceptions of principal caring (Louis and Murphy, 2017). Supportive principal behaviors have been found to strongly predict teachers' trust in the principal; they also influence teachers' trust in colleagues and in students and parents (Demirtaş et al., 2017; Yilmaz, 2004; Yilmaz and Altinkurt, 2012). Various forms of support, such as emotional support, instrumental support, professional support, and appraisal support have all been found to be significant predictors of trust in the principal as well as to organizational commitment (Demirtaş et al., 2017).

In their role as change agents, a sense of benevolence, empathy, and caring is especially important for principals. If school leaders want their staff to engage in making changes in their practice, they must demonstrate that care in ways that are evident to their followers and be understanding of the challenges brought about by the change. Organizational change can be disruptive to a person's sense of wellbeing, as well as their sense of meaning and purpose at work (Bolman and Deal, 2017). It can create feelings of uncertainty as they encounter new processes and procedures for accomplishing their objectives. Communicating clearly about expectations of teachers and what they can expect through each stage of the change process helps to reduce the level of uncertainty that teachers have to cope with. Change also inevitably involves loss (Bolman and Deal, 2017). As they cope with the losses inherent in organizational change, teachers may exhibit any of the five stages of grief (denial, anger, bargaining, depression, and finally acceptance) in response to a change initiatives. It is important that school leaders recognize these reactions as normal responses to grief, and not evidence that those resisting are malevolent or incompetent if they are initially less than enthusiastic at the prospect of doing things differently. Inviting conversations about how teachers are feeling about changes in their school, listening skillfully to their concerns, and expressing empathy are potent means for assisting teachers and staff members to move through the grief process.

Cultivating a culture of care

To cultivate a school-wide culture of care, principals need to attend to the elements of culture, such as norms, stories, ceremonies, and the use of humor (Bolman and Deal, 2017). Establishing shared norms is an important part of developing a shared vision for the school. Changing norms regarding acceptable behavior and speech will likely require some explicit norm-setting conversations. Once these norms are agreed upon, it is a school leader's responsibility to respond to behaviors that fall outside these norms and to teach followers to intervene when these norms are violated. In calling people on their behavior, a leader has to ensure that they abide by the norms themselves, addressing the issues in private and avoiding embarrassing a teacher in front of others. While a school leader may communicate their desire to have a safe and risk-free environment for teaching and learning, when they fail to confront teachers and students on issues of bad behavior in the classroom in a helpful and supportive way, they appear to be giving tacit approval to these behaviors. The stories that are told about people whose actions are admired as well as those told as cautionary tales are another important element of culture that either foster a climate of care or undermine it. One prime area that often needs to be addressed is the tone of how teachers speak about students whose behavior they disapprove of. The ceremonies and rituals of the school also convey the collective values in the school, and warrant attention as to the messages that are being sent. What counts as acceptable forms of humor and play are also areas ripe for exploration in terms of how they can support a culture of care. Humor that involves sarcasm or humiliation is detrimental to a caring culture. Students are attentive to signs that their teachers care about them as individuals and not just about keeping order or moving efficiently through the curriculum (Cooper and Minness, 2014). When teachers speak about this aspect of trust in relation to students, they more often frame it as respect—respect for the shared project of schooling, for the rules, processes, and procedures of school, as well as respect for themselves, for fellow students, for school property, and for educators themselves (Tschannen-Moran, 2014a).

Honesty

Honesty is a fundamental facet of trust. Honesty is evidenced through behaviors that demonstrate integrity, authenticity, and accountability for one's actions (Hoy and Tschannen-Moran, 1999; Tschannen-Moran and Hoy, 1998). Trust requires having confidence that a person's word can be relied upon and can accurately predict future actions. Trust facilitates communication and contributes to greater efficiency when people have confidence in the integrity of other people's words and deeds.

Be honest and authentic

To earn the trust of their followers, school leaders need to earn a reputation for honesty. Integrity speaks to living according to a set of core values or principles, being sincere, and telling the truth. Integrity entails an alignment between a person's words and their deeds. When teachers begin to perceive a discrepancy between their leader's words and actions, trust is undermined. Once a leader's verbal statements are regarded with suspicion, it will be hard for them to regain trust because the spoken word is an essential tool for fostering trust. Having integrity also involves refraining from using one's power to play favorites or to improve one's personal outcomes. A sense of fairness and fair play or what is sometimes referred to as organizational justice is also an essential element of integrity (Yilmaz and Altinkurt, 2012).

Authenticity is expressed when a school leader reveals to followers their true personality and values, as opposed to the projection of an image that masks their nature and intentions. Authenticity involves a willingness to share one's heart, humanity, and foibles with others. School leaders who come across as too guarded in what they are willing to reveal about themselves can be perceived as simply playing a theatrical role, and thus their motivations may be regarded with suspicion. Accountability involves a willingness to take responsibility for one's mistakes and refraining from blaming others for personal failings. School leaders demonstrate vulnerability by acknowledging their mistakes publicly and sharing a plan for growth.

Foster a culture of integrity

If we hope to instill a sense of integrity in our students, then the adults must consistently model these behaviors. Even very young children are observant of instances in which teachers' actions do not align with their admonitions regarding their expectations of student behavior. Just as leaders are expected to tell the truth and keep their promises, teachers must be held to these same standards. One area of promise-keeping that may seem counterintuitive is in the area of threats. Failure to follow through on a threat can be as damaging to trust as failure to keep a promise, even if the misbehaving student is relieved to escape the promised punishment (Tschannen-Moran, 2014a). Thus, teachers need to be cautioned not to make empty threats, and supported to learn more effective ways of winning the cooperation and compliance of students. Cultivating a culture of integrity also means moving away from conveying a tacit image of teachers as all-knowing and infallible. Teachers need to model for students that it is acceptable to say "I don't know (let's see if we can figure out how to find out)" and "I made a mistake (here's what I learned and what I will do next time)."

Competence

Competence is the ability to perform a task as expected, according to appropriate standards. In work that is as strongly interpersonal in nature as education, there are two dimensions to the competence of school leaders: competence with the task and competence with relationships. Both are necessary for trust to develop and be sustained. Competence as an educational leader involves inspiring action, setting and maintaining high standards and pressing for results. School leaders inspire teachers in their commitment to students, but also challenge and support teachers who fall short in their duty to improve their instructional practice, holding teachers accountable in ways that seem fair and reasonable to their staff (Bryk and Schneider, 2002; Chugtai and Buckley, 2009; Forsyth and Adams, 2014; Handford and Leithwood, 2013; Weinstein et al., 2020; Zeinabadi, 2014). Teachers expect principals to efficiently manage their school community and create collaborative spaces, fostering positive relationships that promote cooperation, a spirit of teamwork, and mutual support among colleagues. In particular, principals are expected to play a key role in establishing harmonious working relationships between diverse groups of teachers, such as novice versus senior teachers or regular versus special education teachers (Weinstein et al., 2020).

Mediate conflict

Of the multitude of skills that effective principals evidence, one of the most potent when it comes to building and maintaining trust is to constructively manage conflict. The health of a school community is dependent upon a leader who can mediate the inevitable conflicts inherent in the vital and complex work of schools. Stakeholders rely on educators to be skillful problem-solvers and to demonstrate the requisite conflict-resolution skills necessary to navigate the competing needs and interests of a diverse educational community (Tschannen-Moran, 2014a). Weinstein et al. (2020) found that the principals in their study who were regarded as competent were those who made thoughtful decisions, taking the time to ponder all sides of the issue and the possible consequences of various courses of action, who consulted various stakeholders, and who acted with equanimity, as opposed to acting impulsively. These principals were seen as acting in ways that were fair and just, prioritizing the interests of the school over the interests of any particular group. The teachers interviewed especially emphasized the importance of the way principals made decisions about sensitive matters regarding teachers, such as the assignment of responsibilities or sanctions to address problems such as chronic absenteeism or tardiness.

Principals need to not only have the skills to manage conflict themselves, but to create the structures and provide the training necessary for teachers and students to learn constructive conflict-management strategies as well (Cosner, 2009). When teachers are supported by norms and processes that help them negotiate solutions that meet the needs of all parties, it can help restore trust that

has been broken and also to prevent further breakdowns of trust. Both administrators and teachers need to be aware of the dramatic costs of broken trust. Conflict, resistance, fear, and anxiety can erode trust when people perceive that the actions of others fall outside of established norms and expectations (Tschannen-Moran, 2014a). When trust is broken between administrators and teachers, suspicion and psychological withdrawal are likely to result (Tschannen-Moran, 2014a). When trust is broken between teachers and students, a cycle of punishment and withdrawal or rebellion may result, setting up a dynamic that is deleterious to cognitive and social-emotional development. This is important because the process of repairing broken trust is difficult and costly. Effective educators are on guard to prevent the abuse of power and encourage the cultivation of high-trust relationships.

Organizational change initiatives create conditions that are ripe for conflict. Change processes inevitably disrupt the power dynamics within a school, advantaging some and disadvantaging others (Bolman and Deal, 2017). Even where there is agreement on the goals of the change, there are often differences of opinion as to how to achieve those goals. Breakdowns in trust may emerge around issues of misunderstanding the purpose of the change process, what new behaviors and outcomes will be expected, and how and when the success of the change will be assessed. Honing the competence to engage rather than avoid controversy by skillfully debating ideas is a valuable asset during times of change. Strong norms of civil discourse that guide participants to challenge the strategies, ideas, or thinking of those with whom they disagree, while steadfastly avoiding personal attacks, are important to keeping the dialog constructive (Uline et al., 2003).

Nurture the competence of those you lead

A school leader cannot adequately fulfill their role unless they can lead their teachers and staff to high levels of performance (Tschannen-Moran, 2003, 2009, 2014a). For teachers to be considered competent, they are expected to provide engaging, accurate, and informative instruction, as well as act as diagnosticians who can assess the learning difficulties of particular students and construct effective interventions for struggling students. To support these competencies, a school leader must be consistent in providing clear, specific feedback to followers and in delivering the tools and support necessary for their steady improvement. One of the payoffs of high trust is the development of an organizational culture that supports innovation and professional learning, and a willingness to take risks (Bryk and Schneider, 2002; Cosner, 2009; Daly et al., 2014; Forsyth et al., 2011; Goddard et al., 2001; Louis, 2007). Engaging teachers in instructional rounds encourages a collaborative approach to instructional improvement and when managed carefully has the potential to elevate trust among the faculty.

School leaders must be insistent on and encouraging of improvement, serving as a support system for teachers who are lacking in the adaptive skills necessary to provide high quality instruction to all students. School leaders have a moral and ethical responsibility to safeguard the wellbeing of the students in their school. Therefore, they must respond swiftly and strategically to teachers who engage in teacher aggression that evidences a lack of classroom management skills that undermine trust, such as yelling, using sarcasm and humiliation, as well as group punishments (Riley, 2010; Tschannen-Moran, 2014a). At the same time, they must give people a fair chance to improve before moving toward dismissal. The evocative coaching model suggests building on teacher strengths and then inviting them to design experiments around ways they want to or need to improve their instruction (Tschannen-Moran and Tschannen-Moran, 2020).

Reliability

In a situation of interdependence, when something of importance is required from another person or group that impacts joint outcomes, trust is evidenced by a sense of confidence that the trusted person will come through with what is needed on a consistent basis, in a timely fashion, and that the work will be of sufficient quality to meet joint standards (Mishra, 1996). If the reliability of the trusted person or group is in question, the trustor must invest energy in making mental provisions for how they will manage in case the other person should fail to follow through on agreements. Reliability involves keeping commitments, keeping promises, keeping appointments, and keeping confidences. Trust may survive a broken promise if a plausible explanation is given along with an apology; however, a pattern of broken agreements will pose a threat to trust.

Foster a culture of professionalism

One of the reasons that trust is so powerfully related to school outcomes is because of the role trust plays in fostering a culture of professionalism (Tschannen-Moran, 2003, 2009, 2014a). The vision for a school as a vibrant professional learning community is characterized by a deep commitment to diagnosing and addressing the needs of individual students through collaboration and joint deliberation. This involves ongoing, rigorous professional inquiry, a collective focus on student learning, data to bolster decision making, de-privatized teaching practice, and reflective dialog (Fullan, 2003; Louis et al., 1996), all of which would require trust. Principals' work to support and enhance collaboration among teachers has been identified as important with respect to the cultivation of collegial trust (Cosner, 2009; Tschannen-Moran, 2001). Greater professionalism has been linked to stronger motivation, greater commitment to shared goals, and a willingness to voluntarily go beyond minimum expectations (Tschannen-Moran, 2003), as well as improved student achievement (Tschannen-Moran et al., 2006; Tschannen-Moran, 2009). If school leaders hope to inspire greater levels of professionalism among their faculty, they need to adopt a professional orientation in their exercise of authority because principal professional orientation has been found to be strongly related to the level of teacher professionalism

(Mitchell and Tarter, 2016; Tschannen-Moran, 2009). School leaders with a professional orientation hold in high regard the professional expertise of teachers and evidence faith in their capability; and because of this, they extend greater trust and give teachers greater autonomy and discretion to exercise their professional judgment in response to the diverse needs of clients (Hoy and Sweetland, 2001; Tschannen-Moran and Gareis, 2015).

In a sense of urgency to bring about improvement in their schools, school leaders may unwittingly fall into a trap that is not uncommon in organizations facing a competitive and changing external environment. Under these challenging circumstances, schools often develop a “rigid response,” becoming more centralized, doubling down on control over teachers, and enforcing rigid adherence to standardized procedures such as curricular scope and sequence plans or scripted curriculums (Daly, 2009). Trust plays a central role in a school’s ability to avoid these counterproductive tactics. High trust school leaders eschew rigid rules and micro-management as means to control teachers, and instead focus on strengthening joint norms of professionalism and a shared vision of a school in which all children thrive (Cosner, 2009). However, these leaders do not abdicate their responsibility for leadership. They engage in coaching and collaboration to bring underperforming teachers into alignment with professional standards, as well as to provide resources to continually extend the professional knowledge of all the teachers in their building (Tschannen-Moran, 2014a).

Openness

Openness as a facet of trust evidences the reciprocal nature of trust, as people garner trust by extending trust. In being open, people make themselves vulnerable to others by sharing information, influence, and control (Zand, 1997). Leaders who are guarded with the information they share provoke suspicion as people wonder what is being hidden and why. Withholding important information is a strategy that leaders may use to maintain power or manipulate employees, but it may cost them the trust of their followers (Mishra, 1996).

Be open

Strong principals inspire a shared vision by listening carefully to the hopes and needs of the people they lead. This process is a key opportunity for school leaders to ensure that underrepresented voices in the community are heard and included as part of the vision. A school leader may arrive with a powerful and positive vision, however fail to draw others in. Adopting a strengths-based process, such as appreciative inquiry, can help guide a principal and the school community to craft a vision that is truly shared.

Trust contributes to organizational effectiveness, in part, by creating the conditions for improved communication. In schools where trust is high, communication tends to flow more easily; and, the candor and open exchange of information allows problems to be disclosed, diagnosed, and corrected before they are compounded. In these high-trust environments, mistakes are viewed as opportunities for learning and refinement rather than as occasions for criticism and blame; this makes for greater openness and honesty in the face of disappointing results (Hoy and Sweetland, 2001; Tschannen-Moran, 2014a). Leaders help foster the flow of information to them by being open with communication that flows from them (Bryk and Schneider, 2002; Heyns and Rothmann, 2018). In doing so, school leaders make themselves vulnerable as an act of trust, modeling the courage it takes to confront and discuss difficult issues, especially those likely to evoke an emotional reaction (Kutsyruba et al., 2016; Meyer et al., 2017). When leaders reveal their ideas, thoughts and feelings freely, sharing facts, alternatives, intentions, and judgments, it not only enhances perceptions of trustworthiness but leads to greater openness on the part of subordinates as well.

Trust that involves disclosure of critical and sensitive information of either work-related or personal nature, such as communicating personal insights, task-related knowledge, thoughts and beliefs, problems, concerns, feelings, hunches, and emotional responses to work-related events openly and honestly requires a deeper level of trust than relying only on another’s competence and direction because it is a more active form of engagement. In these situations, trust is more complicated when there is a relationship of unequal power as, for example, between school leaders and teachers (Bryk and Schneider, 2002; Meyer et al., 2017). Those in power can diminish the tension experienced by those with less power through behaviors that signal their intention to foster trust (Bryk and Schneider, 2002). Teachers and staff can be invited to think about what types of obstacles they encounter that prevent them from sharing their views and how they could start to remove these barriers (Cosner, 2009).

Extend discretion and shared decision making

School leaders foster trust through extending trust, with openness in granting discretion and autonomy to teachers, in delegating tasks, and by engaging stakeholders in distributed leadership and democratic decision making. For teachers to work as professionals, they need to be granted discretion to make decisions in their classrooms, even as they are held accountable for the outcomes in student learning and wellbeing (Tschannen-Moran and Gareis, 2015). As professionals, teachers need to learn, grow, and express themselves authentically in their work roles. Autonomy can be promoted by giving teachers more freedom of choice in the way in which instructional strategies are executed, encouraging initiative, and re-designing jobs in ways that enhance meaningfulness and so that work becomes a form of internally motivated self-expression. At the same time, attention should be given to clarifying the expectations and responsibilities that go hand in hand with more freedom, such as the discussion of obstacles to the pursuit of excellence in a frank and fearless manner (Moye and Henkins, 2005).

Delegating important tasks without micromanaging is another way that leaders extend trust in ways that garner greater trust (Heyns and Rothmann, 2018; Tschannen-Moran, 2014a). Teachers who perceived that they were empowered in their work environments and who reported substantial influence in their work environments had higher levels of trust in their principals (Moye and Henkins, 2005). Distributed leadership has been found to be positively related to trust among colleagues and trust in the principals (Adiguzelli, 2016; Beycioglu et al., 2012; Cansoy and Parlar, 2018).

Leaders who engage in authentic forms of shared decision-making in which teachers, students, and parents have genuine influence over decisions help foster trust (Tschannen-Moran, 2001). This is in contrast to leaders who orchestrate contrived processes in which subordinates are asked to give their input to a decision that the subordinates are suspicious has already been made. Democratic principal behaviors in which teacher have the opportunity to express their opinions on issues that concern them and ensuring teacher participation in decisions over which they have expertise and a personal stake have been found to be significantly related to trust in the principal (Heyns and Rothmann, 2018; Kars and Inandi, 2018). One of the ways that trust serves to facilitate school because it expands the zone of acceptance in decisions (Bryk and Schneider, 2002; Hoy and Tarter, 2008). Where trust is low, teachers want a place at the decision-making table in order to guard their interests. When they trust that their interests will be well looked after, they may feel freed to invest their energies elsewhere.

Trusted and trusting

For school leaders to be successful, they must both earn the trust of their followers and foster high trust relationships between the members of their staff, as well as trusting relationships between teachers, students, and their families. Developing strategies for fostering deeper trust are crucial skills for those who would lead schools in our increasingly diverse society. Attention to the five facets of trust, including benevolence, honesty, competence, reliability, and openness provides potent guidance to school leaders for tackling these two challenging and critical objectives.

Elements of parental involvement	265
Having high, but reasonable parental expectations	265
Alterable family variable #2: parental style and the importance of love and structure in the home	265
Alterable family variable #3: social capital	265
How can schools and their leaders help parents further develop these features of family educational cultures?	266
Educators need to become more aware of how great the impacts are of parental family structure, fatherlessness, and parental involvement on students	266
School leaders need to help parents, students, and teachers rediscover the salience of social capital	267
Principals and other school leaders should train school personnel about the most beneficial kinds of parental -expectations, -style, and -involvement	267
Information and direction that school leaders can provide for parents	267
School leaders should make sure parents and students who have added hurdles are sufficiently informed about the advantages of parental involvement	268
Principals and other leaders should train school personnel about the most beneficial kinds of parental involvement for children of different ages	268
School leaders need to do more to involve fathers	269
Concluding thoughts	269
References	269

Increasingly over the past several decades, there has been a growing appreciation by educators, scholars, and those in a variety of leadership positions that family factors are even more important than school variables in terms of influencing academic outcomes of youth (Coleman et al., 1982; Kyriakides and Creemers, 2008; Leithwood et al., 2010). Leithwood and his colleagues, as a result of examining a good amount of data on the topic, have concluded that the family path is perhaps the most salient and explains a sizable portion of the variance in scholastic outcomes. Other prominent studies suggest that family factors may explain about 50% of the variance in pupil achievement (Coleman et al., 1982; Kyriakides and Creemers, 2008). In contrast, research indicates that school factors contribute about 20% of the variance (Coleman et al., 1982; Creemers and Reezigt, 1996). Consequently, an educational leader who recognizes the potential of the family path could emerge as a powerful human catalyst, inspiring students to reach high levels in achievement (Jeynes, 2006b).

Admittedly, in recent decades many principals and teachers have understated the role of the family in school outcomes because they opine that educators can have more of an impact on school variables rather than on home-based ones (Katz et al., 2015; Robinson, 2014). In addition, there is a natural proclivity for educators to study largely education journals and similar publications, sociologists to study sociological ones, psychologists to read psychological publications, economists examine economic works, and so forth (Jeynes, 2012b). If superintendents and principals are to be more efficacious, they need a more interdisciplinary educational purview (Flecha and Soler, 2013; Leithwood et al., 2010; National Academy of Sciences, 2005).

Alterable family variables

With all this in mind, what is key for school leaders to understand is that is that there is a difference between what are *alterable* family variables and those that are unalterable. Unalterable family-related variables are those over which the school has no influence (e.g., parental education and parental income). *Alterable* family variables, sometimes referred to as family educational culture, are potentially open to influence from the school and its leadership. The encouraging trend is that copious researchers believe that there are increasingly more family factors that are alterable than what was thought three decades ago (Hattie, 2009; Jeynes, 2015b).

Five of the family influences that have the most puissant effects on children are: (1) parental involvement in their children’s lives, (2) the degree to which children are loved (Levine, 2012), (3) parental family structure (Jeynes, 2011b; Shirakawa, 2010), (4) social capital, and (5) parental style. Of the five primary ways that family factors can influence pupil academic results, parental involvement, social capital, and parental style are patently the ones on which school leaders can have the greatest impact. It is these three

with that will be addressed in this article, which are the most *alterable*. It should be noted, however, that school leaders can also make a difference in instructing parents on how to lovingly support their children and having their knowledge about the effects of family structure help students and parents (McLanahan and Sandefur, 1994; Wallerstein et al., 2002). Given that it is these three aspects of caregiving that are the most alterable, in this article, the most emphasis will be placed on parental involvement. The reader should keep in mind that when the term “parental involvement” and “parental style” are used this does not refer to any particular family structure(s), but is based on the reality that all children have parents in some sense of the term.

Alterable family variable #1: parental involvement including parental expectations

Parental involvement has become one of the primary areas of research and practice in education today (Hornby, 2011). Parental engagement has been around for many centuries (Harris et al., 2009; Wartman and Savage, 2008). It was present in the teachings of Old Testament and the New Testament, as well as in the daily practices of the Pilgrims and Puritans (Jeynes, 2011b; Wartman and Savage, 2008).

Nevertheless, a series of societal changes in various countries around the world have caused scholars to rediscover parental involvement and this has helped lift it to a central place of scholarship. Beginning around 1963 the divorce rate surged and out of wedlock births also rose precipitously (Phillips, 1988; Weaver and Schofield, 2015). Over the 1963–1980 period, the divorce rate rose consistently for seventeen sequential years (Phillips, 1988; Weaver and Schofield, 2015). Concurrently, by the early 1990s out of wedlock births in the United States had inflated by seven times (U.S. Department of Health and Human Services, 2012; U.S. Department of Justice, 1999). The expressions “latch key children” and “deadbeat dads,” which had been almost nonexistent for the bulk of world history, were by the 1960s and 1970s, at the foreground of interactions among family scholars in many nations (Harris et al., 2009; Jeynes, 2019; Weaver and Schofield, 2015).

Moreover, innumerable children born out of wedlock were oblivious of who their fathers even were (Baskerville, 2007; Mincy et al., 2015; Turkat, 1995). Globally, mothers also entered the workforce in greater numbers and higher percentages than ever before, which translated into parents spending less time with their children, on average, than had been the case in past decades (Shirakawa, 2010; Weaver and Schofield, 2015).

Out of these concerns about the breakdown of the traditional family beginning in about 1963, arose a plethora of concerns about the stability of family. This spawned two branches of research, although one emerged before the other. The first branch focused on the effects of being in a non-traditional family, especially in single-parent families and blended ones (Hampden-Thompson and Galindo, 2015; Moor and Komter, 2012). Much of the purpose of these studies was to educate mothers and fathers about the typical consequences of their children potentially living in a single-parent or blended family. It was hoped, therefore, that if present- and future-parents are cognizant of these statistics, they will hesitate to engage in behavior that increases the likelihood that children will be raised in these family structures. (Moor and Komter, 2012).

The diligence with which family structure was studied was strongly related to the decline in achievement test scores that was transpiring concurrent to the surge in divorce rates (Carter and Glick, 2013; Raymo et al., 2013). Academics concluded that it was highly unusual that the exact period of time in which SAT scores in the US plummeted for seventeen consecutive years, 1963–1980, was identical to the timeframe during which the American divorce rate surged for 17 consecutive years (Carter and Glick, 2013; Stevenson and Wolfers, 2007). Moreover, also in 1963 juvenile -crime rates and -measures of anti-social behavior began to surge (Carter and Glick, 2013; Jeynes, 2007). Studies have shown that when there is an absent parent, children have a higher proclivity to become depressed, suicidal, take illegal drugs, consume large amounts of alcohol, and become sexual promiscuous (Jeynes, 2015a).

The second branch was less focused on results that might prevent children unnecessarily being born into a difficult family situation. Rather, this branch acknowledged that children were being born into single-parent families and wanted to see if high levels of involvement by the custodial parent could compensate for coming from a non-traditional family structure (Jeynes, 2005, 2011a; Tan, 2017). Researchers were also naturally convinced that parental involvement could benefit youth from all family structures, but they were especially concerned about children at risk, particularly as these risks emanated from family structure (Vaughans and Spielberg, 2014).

One of the academic dynamics that caused this second branch to develop is that a number of the most prominent social scientists in the field of parental involvement have also studied family structure, e.g., Joyce Epstein (Epstein, 1989). The developing body of literature on parental family structure’s influence on children therefore eventually produced a new discipline within family studies, i.e., the study of parental involvement (Jeynes, 2011b). This was also a salient advancement, because educators viewed parental involvement as more *alterable* than is parental family structure.

Meta-analytic research demonstrates that parental involvement tends to have a positive impact of about 0.60–0.75 of a grade point (Jeynes, 2003). Parental family structure tends to have an impact of a similar size, i.e., the scholastic difference between youth in intact families in which both the mother and father are present and children from the never married single parent family structure is usually about 0.60–0.75 of a grade point (Jeynes, 2011b). The influence of parental-involvement and family structure have a similar impact on children’s behavior (Shirakawa, 2010; Weaver and Schofield, 2015).

What is vital for parents, educators, and society’s leaders to understand is that parental involvement is not a series of tasks. In other words, it is not simply volunteering at school, attending school functions, checking homework, and establishing household rules. Rather, parental involvement is about love and relationships (Jeynes, 2006a, 2018). It is about bonding with the child. Meta-analytic research has revealed that the most salient components of caregiving, in this sense are largely relational. A meta-analysis is a utilized technique that statistically combines all the research that has been done on a particular topic (Hedges and Vevea, 1998).

That is, a meta-analysis gives a quantitative summary of the entire body of research. Government leaders and academics, in particular, love meta-analyses because rather than read all of the articles and books that have been published on a particular subject, they can just read a meta-analysis on the topic and it summarizes the existing body of research on that topic.

The meta-analyses that have been completed have given considerably greater insight into the workings of caregiving, particularly regarding what components of this engagement are the most efficacious.

Elements of parental involvement

Having high, but reasonable parental expectations

The findings of [Jeynes \(2010\)](#) and [Hattie \(2009\)](#) concur that parents' high, but reasonable, expectations is probably the foremost aspect of parental involvement. Other social scientists agree that having high expectations is the most salient component among all forms of parental involvement ([Klein, 2007](#); [Long and Pang, 2016](#); [Winter, 2006](#)).

Family members should not convey high expectations in a way that rigidly emphasizes, "You will go to Harvard, Oxford, Cambridge, Princeton, or Tokyo University" but rather in a loving and supportive way that subtly communicates that children should do their best ([Jeynes, 2011b, 2018](#); [Phillipson and Phillipson, 2017](#)). As a result of growing up in this kind of an atmosphere, young people understand that in this home it is expected that people give their best effort and aim high ([Klein, 2007](#); [Winter, 2006](#)). School leaders need to communicate to teachers, staff, and parents that one can do more academic and psychological damage to a child by calling them "stupid" than the good that emerges from attending every school function in the year ([Jeynes, 2010](#)). The high expectations that are communicated to youth and adolescents are not to be of the nature that causes undue stress. Instead, they are subtly expressed in parental examples that influence girls and boys on a daily basis.

Many mothers and fathers become involved in the traditional school-based ways, call their child "stupid," and then cannot understand why their child is not performing at his or her potential ([Honore, 2008](#)).

Via meta-analyses it is now evident that the home-based components of parental involvement, such as having high but reasonable expectations of children are, on average, more powerful than the school-based ones ([Harris et al., 2009](#); [Jeynes, 2010](#)). This fact is *extremely important* for school leaders to fully appreciate, because when most educators think of suggestions they can give to fathers and mothers to become more involved, they think of attending school assemblies and events, checking homework, volunteering in school, etc.

Alterable family variable #2: parental style and the importance of love and structure in the home

Research by [Baumrind \(1971\)](#) demonstrates that youngsters develop best if they are reared in a home atmosphere that has a balance of love and structure. Children progress best in an environment in which they feel loved ([Coleman, 2012](#); [Levine, 2012](#)). Youths thrive in circumstances which they feel loved and valued ([Coleman, 2012](#); [Levine, 2012](#)). When they are frequently criticized and put down, it hinders their ability to perform at their highest levels ([Stipek and Seal, 2001](#); [Sax, 2009](#)). As part of the expression of this parental love, mothers and fathers also need to raise their children to exercise self-discipline so that they complete their assignments on time, etc ([Hagelin, 2005](#); [Stipek and Seal, 2001](#)). Parental love also plays a prominent role in helping children to succeed later in life ([Jeynes, 2016b](#); [Levine, 2012](#); [Stipek and Seal, 2001](#)). Parental engagement and making it a priority to keep the family together are probably two of the major expressions of love that caregivers can show ([Hagelin, 2005](#)). Nevertheless, parental love can be manifested in numerous ways and can be a marvelous asset and source of strength to children as they develop.

Sadly, the word *love* is probably the most feared four-letter word among scholars and often in schools as well. However, studies suggest that if schools reach out to children and families in an attitude of love, caregivers are much more likely to become engaged in their children's schooling ([Mapp et al., 2008](#)). Studies utilizing nationwide data sets and meta-analyses indicate that part of the reason why parents become more involved- and students excel more-at religious schools than in public schools is because they feel loved more ([Jeynes, 1999, 2012a](#)). If school leaders create an atmosphere of both love and structure in their schools and instruct parents to become the same way, students and their families will tend to flourish.

Alterable family variable #3: social capital

It is important for educators to acknowledge the social capital to which students have access.

Social capital is defined in the Collins Dictionary as "the network of social connections that exist between people and their shared values and norms of behavior among people, which enable and encourage mutually advantageous social cooperation ... and a sense of belonging." There are many sources of social capital, but the two that are most often referred to are the family and houses of worship ([Coleman et al., 1982](#); [Jeynes, 1999](#)). James Coleman and his colleagues often pointed to the home and the houses of worship as sources of social capital. Technically, Coleman and his colleagues examined churches and synagogues, but one can argue it may well apply to other houses of worship as well. He also believed that one of the strengths of religious education was its ability to bring these two sources of social capital together in order to better educate children ([Coleman et al., 1982](#); [Halpern, 2005](#)). Coleman claimed that one of the reasons why schools of faith did so well in providing scholastic and behavioral tutelage for pupils is because these schools encourage parental participation and hence bring together family- and faith-based sources of social capital ([Coleman et al., 1982](#)).

The power of the family is manifested not only in the atmosphere in the home, but also in various practices of the family. *Communication* is essential if one is to maximize source of social capital that the family is. The communication between parents and their children needs to be both frequent and supportive in order for it to maximize its potential to do good (Chapman and Campbell, 2016; Meyer, 2009). In order to enhance parent-child communication school principals and teachers must not only convey to fathers and mothers just how important this is, but they must also demonstrate exemplary behavior to the children. School staff can talk about communication all they want, but if they do not communicate much or denigrate others when they do express themselves, their words will have little impact (Jansen, 2011). Caregivers can come to a comprehension of this fact, because one of the chief peeves of low-SES parents is that educators speak down to them (Jeynes and Littell, 2000). In loving communication, people view others as more important than themselves (Chapman and Campbell, 2016). If caregivers comprehend that they do not like educators speaking down to them, they will more easily fathom why similarly children do not enjoy their parents speaking down to them.

Aldrich (2012, p. 2) stated in his book *Building resilience: Social Capital in Post-Disaster Recovery*, "I argue that higher levels of social capital—more than such factors as greater economic resources, assistance from the government or outside agencies, and low levels of damage—facilitate recovery and help survivors coordinate for more effective reconstruction." Aldrich (2012, p. 9) continues by stating that, "Empirical studies of the effect of aid and government expenditure have failed to provide evidence of a causal link between more aid money and enhanced recovery."

Robert Putnam (1993) helped popularize the concept in his book, *Making Democracy Work*.

Putnam argued that social capital yielded a type of *civic virtue*. Putnam (1993) believed that there were three aspects of *social capital*: trustworthiness, norms, and networks. All of three of these aspects provide support for students. It helps them develop strong connections with their family, friends, and institutions that are a source of values and inner strength. Often families, friends, and houses of worship provide some of the strongest sources of social capital. In the case of the house of worship, for example, there are values and norms that are taught, networks and connections that are made, and a sense of trustworthiness that results. Similarly, in the case of the families there are certain commonalities that exist in the family, especially to the degree that it develops and unites over a sense of shared values.

Both faith and family often provide a real solid foundation of social capital. They both provide youths a sense of principles and guidelines regarding how the world works and, in contrast, how it should work. James Coleman highlighted the role of religious worship centers in providing social capital both through worship services and their many schools (Coleman et al., 1982). According to Coleman, churches, synagogues, and houses of worship provide children a foundation of an emphasis on love of God and love of neighbor as the most important qualities that one can have, in the midst of a world of largely self-serving people (Gatto, 2001). According to Coleman and his colleagues, churches, synagogues, and faith-based worship schools provide those houses of refuge that people, particularly children and adolescents, in order to maintain their strength to do well in school and in life (Coleman et al., 1982). Families also provide a source of strength and a close network that is a source of great support for youths (Bronfenbrenner, 1979). One of the most important expressions of mothers and fathers providing social capital to help their offspring in school is reading with them. Research evidence indicates that the sooner parents begin to read to their children the better. As a result, it is advisable for family reading to begin well before the child knows the alphabet (Risley and Hart, 2006). Some parents even initiate reading to and talking with their children at birth or even before they are born (Risley and Hart, 2006).

How can schools and their leaders help parents further develop these features of family educational cultures?

With the principles examined in mind, there are actions that teachers and school leaders can take to help shape family educational cultures in such a way that students will benefit.

Educators need to become more aware of how great the impacts are of parental family structure, fatherlessness, and parental involvement on students

School Superintendents, principals, and other school leaders need to understand that family factors can make children either stronger or more vulnerable. Boys from single-parent families are much more likely to end up in gangs than their counterparts in two-parent families (Gerdes, 2012; Popenoe, 2009). Generally speaking, about 90% of adolescents and pre-adolescents in gangs come from single-parent families (Jeynes, 2011a, 2012a; Popenoe, 2009). Psychologists assert that this situation exists, because these youths are looking for a surrogate-father (Popenoe, 2009). As Blankenhorn (1998, p. 88) observes, "Put simply, we have too many boys with guns primarily because we have too few fathers."

When educators are familiar with these realities, they can take action to provide some support that includes (1) helping support parents and the family, (2) taking on certain parental roles that will help the child; and (3) becoming aware of the fact that some people in the world will take advantage of vulnerable students and lead them into trouble. It is a calling to serve and minister to children (Jeynes, 2011b).

Educators need to more expeditiously and correctly identify the trials that children from single-parent-, blended-families, and homes with low levels of parental involvement encounter and how it can ultimately influence their schoolwork, ability to focus, penchant toward depression and even suicide, school behavior and rates of suspension, and likelihood of joining a gang and committing criminal acts of violence (Gerdes, 2012; Jeynes, 2007). Granted, these truths may be unpleasant to digest, but thwarting them or steering a youth away from such activities can often be the most fulfilling aspects of K-12 leadership (Gnezda, 2005; Shore, 2002).

There are a number of reasons why children flourish better in intact families rather than in single-parent families. First, family dissolution through divorce, the death of a parent, or a tenuous relationship that comes to an end are often very distressing experiences for children (Moor and Komter, 2012; Pew Research Center, 2007). Second, marital break-up nearly always causes a drop in family income (Barigozzi et al., 2019; Hampden-Thompson and Galindo, 2015; Pew Research Center, 2007). Third, youths often question the extent to which they are loved when parental relationships collapse (Roberts, 2014; Wallerstein et al., 2002). Fourth, as a result of family break-up, overall children nearly always spend less time with their two parents (Pew Research Center, 2007; Wallerstein et al., 2002).

One of the best ways that instructors can try to compensate for some of the challenges that these young people face is to encourage families to practice parental involvement. Even if a pupil is from a non-intact family, some of the disadvantages can be compensated for if parents are willing to become engaged in their children's schooling and overall education (Jeynes, 2005).

School leaders need to help parents, students, and teachers rediscover the salience of social capital

Forty years ago it was fairly popular for people to talk about the importance of social capital, in large part because of the work of John Coleman and his associates (Coleman et al., 1982). Coleman conducted his research at just the right time. From 1963 to 1980 divorce rates in the United States skyrocketed, the Bible and prayer were removed from the public schools in 1963, and the 1960s and early 1970s in many ways epitomized what it meant for a society to be in turmoil. The assassination of President Kennedy, Martin Luther King, and Robert Kennedy rocked the nation. President Lyndon Johnson sending well over half a million troops to Vietnam and Watergate divided the country (Hunt, 2011). This period was one in which it appeared that the country had lost its moral compass. Coleman's research of the mid-sixties through the early 1980s, in particular appeared to be a call for the nation to regain its bearings, as well as rediscover its foundations and the values that made it great (Coleman et al., 1982).

However, the days when social capital had a prominent place in intellectual discussions have passed. Many caregivers, students, and their families are no longer familiar with the term. Educators often lament the fact that it is easier for them to blame teachers, politicians, and societal factors at large for their children seemingly not living up to their potential than to recognize that the solution of social capital is often not much farther than their own breath (Aldrich, 2012). Therefore, there is a great need to reintroduce this concept and describe the ways that the families can help their children.

A substantial number of social scientists have asserted that they believe that the social capital available to children in the home can give them a decided advantage in their scholastic potential and performance (Coleman et al., 1982; Halpern, 2005). Social capital largely consists of culture, relationships, and moral foundations such as the work ethic that are a source of strength for youngsters (Coleman et al., 1982; Halpern, 2005).

Parents help set a moral tone and foundation for their children in the home. Over the last several decades, there has been a tendency for parents to view the instructor's responsibilities as increasingly greater and their own responsibilities as more and more narrow. In the midst of these trends, many parents do not realize the social capital that they can provide, their house of worship can provide, etc. These centers of worship can provide a sense of purpose in life, which can inspire a strong work ethic (Aldrich, 2012; Coleman et al., 1982). Many churches, for example, also have tutoring services that can help pupils thrive and achieve new heights in school. Many mothers and fathers are not aware of these opportunities (Jeynes, 2011a). Educational leaders can make them more aware of such opportunities and how to capitalize from them.

Principals and other school leaders should train school personnel about the most beneficial kinds of parental -expectations, -style, and -involvement

It was likely a misstep when scholars chose to examine school-based parental involvement well before they gave careful examination to its home-based expression. Having stated this, the error was an understandable one, because academics felt they could control classroom environments far more easily than they could home environments (Harris et al., 2009; Sax, 2009). As a result, teachers often highlight school-based components of family engagement. They also tend to underestimate the primacy of parental expectations and parental style, which usually have their greatest impact at home. However, meta-analytic data indicate that home-based expressions of parenting such as high, but reasonable, expectations and rearing style are actually more powerful and more influential than other components of family rearing. Hence, school leaders need to adjust their advice to parents and teachers, so that it matches the data. It is not only vital that leaders direct family members to understand that parenting is salient in a general sense, but also convey to parents that home-based aspects of parental participation are usually the most vital (Jeynes, 2017, 2018).

Information and direction that school leaders can provide for parents

There is copious amount of information and advice that educators can provide for families that can help them familiarize themselves with the full benefits of mother and father engagement. To be sure, in order for teachers to be efficacious in supplying this advice, they themselves need to be cognizant of parenting research. Unfortunately, the reality is that most school leaders and instructors are not familiar with the body of research in this discipline (Henderson and Mapp, 2002; Jeynes, 2011b). Their knowledge is often limited. As a result, they direct parents into the standard expressions of school-based parental involvement, with little or no emphasis on parental expectations and parental style (Jeynes, 2011a).

It is therefore absolutely necessary for educational leaders to become well versed in the most comprehensive studies examining the benefits of parenting, which usually means those that utilized meta-analyses or the examination of nationwide data sets (Hedges and Vevea, 1998). Once leaders familiarize themselves with the research and literature on parental engagement, they can offer guidance on the following points. First, it is important that educators communicate to mothers and fathers that both the family-based and subtle components of parental involvement are generally the most important (Jeynes, 2010). The vast majority of parents are not aware of this fact. Moreover, they really are not familiar with the aspects of engagement that have the greatest impact (Henderson and Mapp, 2002; Jeynes, 2011b). They are unaware of just how key it is to have high but reasonable expectations, a balanced parental style, and upbuilding communication.

Second, school leaders need to convey certain messages to teachers, for them to then share with parents. Among them are these. For example, mothers and fathers need to understand that the parenting done at home regarding having high but reasonable expectations and the style of parenting that they engage in is generally considerably more important than the parenting they exhibit at school. School leaders need to instill in their instructional staff the salience of love. Johann Pestalozzi (1898, 1916), an educator who had a major influence in the emphasis of early public schools and considered one of the finest educators ever, asked an important rhetorical question. He asked why was it that children learned best at home than in any other environment. Given that the question was a rhetorical one, Pestalozzi (1898, 1916), answered his own question and asserted that the reason was because children were loved at home. High and reasonable expectations and a parenting style that combines love and structure are some of the most important qualities that a parent can have.

School leaders should make sure parents and students who have added hurdles are sufficiently informed about the advantages of parental involvement

It is also important for school leaders to communicate to families of low socioeconomic status, people of color, immigrants, and other groups who might be more hesitant to believe that they can contribute as much as other parents, that *parental involvement works for all groups* (Jeynes, 2016a, 2017; Jeynes and Littell, 2000). Even if fathers or mothers work two jobs, because the most salient forms of parental involvement are home-based and subtle, they can make a huge difference. If the parents are immigrants it is not easy, particularly if their first language is not English (Klein, 2007). However, school leaders can instruct teachers to reach out in love so that especially if the language is common among students, the teacher can, via the parent, learn some of the language and in turn teach the parents more English.

Principals and other leaders should train school personnel about the most beneficial kinds of parental involvement for children of different ages

The results of the meta-analysis provide some excellent guidance for educators in *dealing with children of different ages*. These findings indicate that the type of parenting that is the most effectual during a student's elementary school years is often not the most suitable for the secondary school years (Hulbert, 2003; Steinberg, 2004). It is interesting to note that family activities such as checking homework, establishing household rules for when it is time for work and leisure, and attending student classes and other school functions are associated with higher scholastic outcomes to a statistically significant degree among elementary school students, but have little or no relationship with these outcomes at the secondary school level (Jeynes, 2011b). The reality is that younger children are often far more at ease with direct parental participation than are adolescents (Cherlin, 2008; Graber and Brooks-Gunn, 1996). Adolescents, on the other hand, generally feel more comfortable with less direct parental intervention (Downey and Eccles, 2005; Fuller, 2009).

Unfortunately, most parental involvement strategies pay little or no attention to the age of the students. The overwhelming percentage of parental engagement strategies are based on the pupil's elementary school years rather than the subtler aspects of that involvement that become more salient at the secondary school level.

Principals and superintendents, can also provide families beneficial advice when it comes to rearing practices that are best for different ages of children (Hulbert, 2003; Steinberg, 2004). One of the greatest lessons a mother or father can internalize is that just because you are a good parent with a five year old does not mean that you will be a good parent with a fifteen year old. Helpful parenting practices are not static, but change to some degree depending on the age of the child. Social science statistical analysis now supports this declaration. Over the course of the last three decades, a substantial body of research has accrued indicating that parental involvement has a considerable degree of impact at both the elementary and secondary school level (Green et al., 2007; Domina, 2005; Englund et al., 2004). Meta-analyses indicate that the most effective parental involvement components are not the same among young children versus adolescents (Jeynes, 2011b). That is, more overt expressions of parental involvement are associated with higher academic outcomes among elementary school students, but are no longer associated with these better results when students reach high school (Jeynes, 2005, 2011a). By the time students attain secondary school, virtually all the aspects of parental involvement that yield higher academic outcomes are subtle components (Jeynes, 2011b). School leaders need to adequately disseminate this information to parents.

School leaders need to do more to involve fathers

In reality, when education leaders use the term “parental involvement,” what they often mean is “mother involvement” (Nielsen, 2019, 2020). This is especially the case when there has been family dissolution (Nielsen, 2019). Often, in this case, educators virtually ignore the fathers and in this practice it is often the children that suffer the most (Nielsen, 2019, 2020). However, if educators are to be people who are filled with integrity and keep their word, they need to do all they can to draw in *both* parents (Nielsen, 2019).

A meta-analysis on the effects of father involvement indicates that nearly half of the benefits of parental engagement is generated from dads (Jeynes, 2015b). Great Britain may practice the most outstanding program to inspire father involvement. The UK’s *Sure Start* program appears superior to similar initiatives in the United States, such as *Head Start* (Potter and Carpenter, 2008).

The first way *Sure Start* is superior is that it demonstrates a sophisticated approach to welcoming father involvement in that it seeks to combat sexist stereotypes that portray males as not very nurturing. Potter and Carpenter (2008) reported that fathers often complained that one reason they tended to eschew school-parent gatherings is because they felt that the women stared at them in a judgmental way. *Sure Start* attempts to improve the situations for fathers by making teachers more aware of these stereotypes and the paternal perceptions of them. *Sure Start* advocates also point out that many school leaders subtly impede father participation by providing knitting classes and aerobics workouts, which are overwhelmingly attended by mothers, but not providing other activities that encourage fathers to come to the schools. *Sure Start* has seen a surge in fathers coming to the schools by providing weightlifting classes (Potter and Carpenter, 2008).

Second, *Sure Start* focuses more specifically on drawing in fathers into the schooling process. *Sure Start* advocates that special consideration be given to non-custodial fathers. Nevertheless, these advocates also assert that fathers in two-parent families need to understand their importance in the family. *Sure Start* is designed to communicate to both single parent and two-parent fathers how they can help lift the educational outcomes of boys (Potter and Carpenter, 2008).

Concluding thoughts

For centuries parents and educators have known that the family culture has a major impact on the scholastic outcomes of their children. Social scientists today, via their various studies and theories, are simply confirming this overall reality that the general population has known for centuries. When parents are determined, in both their actions and attitudes, to become more active in their children’s education, they can make a profound difference in how they their offspring do in their classes (Domina, 2005). If school leaders implement the recommendations given in this article, mothers and fathers have a tremendous opportunity to reach their full potential in helping their children excel in their studies. To the extent that school leaders identify what aspects of parenting can make a difference and implement strategies that will make a difference, the impact will probably be greater than what most school officials can currently appreciate. Moreover, it is particularly clear that if school leaders have a deeper appreciation of some of the components of educational culture that are especially underutilized, the difference it would make could be particularly outstanding. For example, social capital can be a powerful influence, but is currently not particularly in vogue. Second, it is extremely rare that educators at any level appreciate and discuss how the effectiveness of different aspects of parental involvement are especially salient at different age levels. Third, few educators have deep discussions of how best to raise children, especially when it comes to addressing high and realistic expectations for children and the importance of a balanced style of parenting. Fourth, few school leaders fully appreciate the important role of fathering.

Previously in this article, it was emphasized that love and relationships are at the heart of effective parenting. Children are smart and can usually tell if their parents love them and want to foster and strengthen a relationship with them (Jeynes, 2007). Consistent with this logic, families can tell if teachers and school administrators truly care about them (Mapp et al., 2008). A school can promote all the efficacious programs that they desire, but unless families perceive teachers and principals as loving and caring individuals who want to build relationships, such programs will have little impact (Mapp et al., 2008). Truly, sincere school leaders can make a difference.

Three factors with especially significant effects on student achievement are teacher quality (Wayne and Youngs, 2003), school leadership (Leithwood et al., 2020), and family engagement (Smith et al., 2021). Here, we focus on the intersection of school leadership and family factors. In the past, school-centric foci and the practices of dominant families shaped definitions of parental involvement and family engagement (Ishimaru, 2014, 2020). Thus, we begin by using a critical lens to define and describe models of family engagement. Next, we take a historical look at the evolution of family engagement in a Western context and use an international perspective to discuss promising practices globally. Here, we take an international perspective and elucidate promising levers and pathways, such as targeted leadership standards for family engagement, equity-based theories that inform models of family engagement, and results-based system reform efforts such as community schools.

Impacts of family engagement and school leadership

Family engagement in children's education correlates positively with a range of positive outcomes for students, such as attendance, achievement, and social and emotional wellbeing (Jeynes, 2018, 2021; Ma et al., 2016; Jacobson and Blank, 2015a,b). Schools shape and are shaped by their communities. In other words, context matters. Specifically, social and economic conditions impact families, communities, and schools. Educational equity gaps based on culture, race, ethnicity, language, sexual orientation, and class (Ishimaru and Galloway, 2014; Leithwood, 2021) can be mitigated or worsened, depending upon the internal compass, values, knowledge, and skills of school leaders (Briscoe and Pollock, 2017; Leithwood, 2021). School leadership impacts students' lives both directly and indirectly (Leithwood et al., 2020). Evolving leadership standards, enriched preparation for aspiring principals, and more nuanced evaluation of practicing principals acknowledge the importance of partnering with families and communities to enhance equitable access to education (Alberta Teachers' Association and Canadian Association of Principals, 2014; Young and Perrone, 2016).

In a volatile, uncertain, complex, and ambiguous (VUCA) world, there is room for hope and opportunity for change. Multiple sources of injustice continue to impact the educational experiences of students and families around the world. Social justice literature identifies systemic racism, socioeconomic, digital divides, and colonialism as factors contributing to structural injustice.

We describe structural injustice as associational, distributive, and cultural. The term associational refers to the ability of all groups to govern, participate, and make decisions that affect their lives (Gerwitz and Cribb, 2002; DeMatthews et al., 2016). Thus, associational injustices include marginalized communities with limited (or no) participation and/or ongoing mistrust with social groups that engage with decision-making practices. Distributive injustices include inadequate housing, health care, education and economic opportunities. Cultural injustices include racism, nonrecognition or invisibility, deficit perspectives, othering, stigma, and exclusion.

We conceptualize colonialism as a structural injustice encompassing associational, distributive, and cultural factors (Gerwitz and Cribb, 2002; DeMatthews et al., 2016). Horvath (1972) defined colonialism as: "a form of domination—the control by individuals or groups over the territory and/or behavior of other individuals or groups"; as possessing "political" and "economic variables"; and as a "culture-change process" (p. 46). Horvath differentiated colonialism from imperialism by the presence of "large numbers of settlers" with aims of "assimilation" (p. 47). Battiste (2004) further defined colonialism to include "cognitive colonialism" (p. xvi) that described the centering of Western values and forms of knowledge in education. All of these factors represent structural

injustices that are aggravated further by global stressors, such as pandemics, climate change, political and economic instability, and violence.

These intersecting factors continue to shape present systems and in many cases oppress non-dominant families. We define nondominant families as “those impacted by systemic oppression, such as marginalization based on race, class, language, or immigration status” (Ishimaru, 2020, p. 8). In some instances, the perspective of parents is not sought or acted upon. However, some policy makers, systems, and schools are shifting the narrative and taking collective action. This view of nondominant families is applicable to a wide variety of contexts at an international level. Such an approach accentuates the importance of power differentials and context.

Defining family engagement

We conceptualize family engagement as full, equal, and equitable partnership among families, educators, and community partners to promote children’s learning and development from birth through college and career (Mapp and Bergman, 2021). Rather than presenting this definition as the most ideal or authentic form of family engagement, we view it as an aspirational definition located on one end of the continuum. This definition of family engagement was co-created with families, policy makers, educators, and community leaders as part of collective efforts to enact more liberatory (free of dominance), solidarity-driven (in union and fellowship), and equity-focused (fair and just) family engagement practices in schools (Mapp and Bergman, 2021). This approach views family engagement as a practice—not a program—that is interrelated with teaching and learning, health and wellbeing, neighborhood development, and overall community uplift, particularly in relation to nondominant families. With this equity-based view of family engagement in mind, we now turn to models of family engagement.

Models of family engagement

The above definition builds upon and expands previous models of family engagement, such as Joyce Epstein’s (1987), Epstein and Dauber (1991) influential model of parental involvement which outlines six categories by which educators can involve parents in their children’s education (parenting, communicating, volunteering, learning at home, decision-making, and collaborating with the community). Epstein et al. (2018) extended the term “parents” to include guardians, foster parents, and extended family members and argued for “overlapping” rather than separate spheres of influence in a child’s life. In other words, children learn at home, in school, and in the community; thus, schools and families must partner. By its’ very structure, early versions of the Epstein model reflected uni-directional ways of thinking about families and outlined school-centric avenues to involve parents. Later versions of the model elaborated examples of working *with* families and identified specific challenges to implementing the model. Terminology in the field shifted from the phrase “parental involvement” to “family engagement,” reflecting awareness of (a) the multiple configurations of family and (b) the need for family agency and autonomy, and (c) the need for bi-directional communication, decision-making, and action (Weiss et al., 2018).

In line with this shift in terminology, Hong (2011) described three phases or “a cord of three strands” (induction, integration, and investment) that characterized successful community-based family engagement. Hong (2011) contended that equitable change involved working across ecologies of home, school, and community to make a cultural shift that honored the ways in which parents contribute to their children’s education. Similarly, Auerbach’s (2010, 2012) model of family engagement provided guidance to school leaders by outlining a continuum toward authentic partnerships with families. Elements of the continuum include how leaders position families and community organizations and the extent to which leaders commit to co-constructing goals and reducing power differentials between educators and families. Auerbach’s model identified authentic family and community engagement as a matter of social justice.

At the same time, education scholars of color propose equity-based conceptualizations of family engagement. For example, Ishimaru (2019) calls for family engagement strategies to redress “asymmetrical power dynamics, and cultural, class, and language divides” (p. 351). Alameda-Lawson and Lawson (2019) proffer a relational model of collective parental engagement (CPE) that seeks to engage groups of parents in the community and school by cultivating change at individual, social, and institutional levels. Hernandez et al. (2014) emphasize the racial identity development of educational leaders, thus leading them to prioritize racial identity development in students and culturally responsive ways of engaging families.

In summary, these models illustrate the need for families to exercise agency in deciding how, when, and where they will engage in their children’s education. In other words, there is no “culture-less” or isolated family engagement. Thus, in what follows, we take a historical approach that takes into account power dynamics and contextual factors that shape family engagement and school leadership.

Historical look at family engagement: pendulum swings of power and control

Prior to discussing current issues in and future directions of family engagement and school leadership, it is important to consider historical accounts that reveal cyclical patterns and ongoing issues in this focus area. Therefore, in this section, we turn our attention

to parent involvement from a historical perspective and utilize the United States as a contested terrain with shifting power dynamics over time.

In a historical perspective of parent involvement in American public schools, [Hiatt-Michael \(1994/2000\)](#) highlights the “pendulum swings” from parent involvement in the home and parent control of schools, followed by local control of education, to the eventual bureaucratic factory model schools of the industrial revolution. Hiatt-Michael also describes how many schools in the colonial period were organized along social class, but later “the shift from parent education to public education occurred first in Europe and then was transmitted to America” (p. 248).

After the Revolutionary War era, American leaders promoted tax-supported universal education for all children (including the poor), with particular attention to teaching reading, writing, and rhetoric to America’s European immigrants. Subsequently, America’s public school system functioned as tools of socialization and assimilation toward a “common culture,” particularly in heavily populated urban cities ([Pulliam, 1987](#); [Spring, 1986](#); [Tyack, 1974](#)). Later, there was a rise in compulsory education and child labor laws, followed by the development of school bureaucratization and the professionalization of teachers ([Hiatt-Michael, 1994/2000](#)). This was the time of the single-room schoolhouse with children of multiple ages that was organized and operated by a locally hired teacher. Soon after, “children were classified by grade” (p. 252) as part of a graded school plan.

During this time period in America’s public schooling, “the increasing separation between parent control and public school was perceived by parents,” and mothers (mostly middle and upper class) sought intervention. This led to the National Congress of Mothers (NCM) in 1897, a convening which later turned into what is now known as the Parent Teacher Association (PTA). According to [Davies \(2000\)](#), the PTA served to Americanize newcomers to the country and to teach middle class parenting. As parents regained more control, a growing number of court cases ensued, including landmark court cases such as *Mendez v. Westminster* (segregation of Mexican Americans in California), *Brown v. Board of Education of Topeka* (segregation of Black and White children in US) and *Lau v. Nichols* (bilingual education in the US). Subsequently, “many parents became so enraged” with desegregation practices “that they removed children from public schools and enrolled them in private schools, created new schools, or began home schooling” ([Hiatt-Michael, 1994/2000](#), p. 256). Now, in the contemporary information age, the “pendulum appears to be swinging back again ... toward schooling which increasingly involves parents” (p. 256). There is an increasing emphasis on collaboration with the aim of better understanding and supporting families and schools as interdependent (rather than independent) entities (p. 257). Moreover, [Baquedano-López et al. \(2013\)](#) describe how inequities in parental and community involvement in US schools are longstanding and persisting issues. In the United States context, schools are essentially run by dominant populations and there is no cultureless family engagement; it is integral part of what anthropologists and academics refer to as “culture wars” in local and global contexts.

In summary, a historical look reveals that leadership and family engagement practices function within a complex and dynamic continuum: at times “at odds” with each other (high tension), at times in harmony (low tension), and most of the time in a state of productive struggle (somewhere in the middle). To this extent, we see how pendulum swings among multiple stakeholders with competing interests are an ongoing issue in school leadership and family engagement in education. Next, we turn our attention to the professionalism of school leaders as signaled through standards, the influence of Western standards in international contexts, and the extent to which standards highlight the importance of leaders’ work with families and communities.

Leadership standards related to family and community engagement

The influence of Western leadership standards in policy borrowing

We begin by discussing the purpose, evolution, and influence of leadership standards in Western and Anglophone settings (US, Canada, and UK), follow with a discussion on how select countries around the world have “borrowed” and adapted these standards, and conclude with a particular focus on standards guiding educational leaders’ work with families and communities.

Standards, both for in-practice educational leaders and for educational leadership preparation programs, create common expectations for the preparation and work of principals and, in many cases, form the basis of their evaluation. The [Center for Study of Policies and Practices in Education \(2013\)](#) performed a comparative study of standards in countries belonging to the Organization for Economic Cooperation and Development (OECD) and contend that standards “clarify and provide focus to the principals’ function” (p. 49). Leadership standards are not without critics. For example, [Riveros et al. \(2016\)](#) contend that standards create a false optimism that the agency of leaders can overcome systemic and structural obstacles. [Weinstein and Hernández \(2016\)](#) argue that standards created in Western context and culture cannot be transplanted to other contexts and cultures, such as those found in Latin American countries. [Carrasco et al. \(2021\)](#) contend such standardization decenters educators’ professional judgment and attempts to provide cookie cutter solutions to unique school environments. Furthermore, scholars [Moorosi \(2020\)](#) and [Davis et al. \(2015\)](#) critique the “colour-blind” language of standards documents. In a similar vein, [Antony-Newman \(2019a,b\)](#) analysis of educational policy documents in Ontario reveals narrow definitions of parent involvement laced with discourses of barriers and parental deficiency (p. 143). Moreover, issues of inequality are omitted rather than positioned as central in policies and practices. However, together with the intrinsic values school leaders bring to their work ([Gu et al., 2018](#)) leadership standards hold the potential to improve the lives of students and families. Here, we examine the signaling of educational policy makers through standards and the relative importance placed on engaging families and communities in children’s education.

In the 1990s, the standards movement emerged in Western and Anglophone countries and spread rapidly to non-Anglophone countries ([Berkovich and Bogler, 2020](#); [Flessa et al., 2018](#)). In 1996, the US based Interstate School Leaders Licensure Consortium

(ISSLC) created a set of six standards for school leaders. Standard 4 addressed principals' work with parents and families: "Collaborating with family and community members, responding to diverse community interests and needs and mobilizing community resources." Recently, the National Policy Board of Educational Administration (NPBEA) revised these professional standards and reworded the standard addressing family and community engagement (Young and Perrone, 2016). "Effective educational leaders engage families and community in meaningful, reciprocal, and mutually beneficial ways to promote each student's academic success and well-being" (National Policy Board for Educational Administration, 2015). In addition, cultural responsiveness with an emphasis on equity earned its own standard, highlighting the need for an assets-based and holistic approach to educational leadership (Murphy et al., 2017). Thus, in the US context, leadership standards promoted working *with* families and communities as integral to the work of school leaders.

In Canada, the Ontario Leadership Framework, introduced in 2006 and revised in 2013 in response to evolving leadership research (Leithwood, 2012), outlined five core capacities for school leaders (setting goals, aligning resources, promoting collaborative learning cultures, using data, and engaging in courageous conversations). In a more fulsome description, the School Level Leadership model detailed an inclusive approach to "Building productive relationships with families and communities" that included welcoming parents, viewing them as partners, building trust, and working with diverse families. Similarly, in the United Kingdom (UK), National Standards for Headteachers outline 10 broad areas of responsibility, and the ninth standard, Working in Partnership, states that headteachers must "forge constructive relationships beyond the school, working in partnership with parents, carers and the local community" (UK Government, 2021). In sum, leadership standards in three Western and Anglophone countries specifically signal the importance of partnering with families and communities.

International leadership standards and family engagement

Non-Anglophone education systems around the world quickly adopted or adapted standards to their own contexts or created their own educational leadership standards (Berkovich and Bogler, 2020) with a greater or lesser degree of guidance regarding the work of school leaders with families and communities. Emerging research on the professionalization of school leadership in non-Anglophone countries *and* space constraints limits our discussion to selective and illustrative examples. Next, we consider a cross-cultural analysis of leadership standards in China (Wei, 2017); an examination of standards' adoption in eight countries/subregion in Latin America (Weinstein and Hernández, 2016) with a particular emphasis on Chile, and a critical view of the standards document informing the work of South African school leaders (Moorosi, 2020).

The Chinese Ministry of Education adopted a set of professional standards for school leaders in 2013 that were influenced by the ISSLC (2008) standards. Wei (2017) performed a cross-cultural analysis of these standards and concluded that, while there were similarities between the US and Chinese standards, significant differences could be explained by unique cultural and national contexts. A crosswalk between the ISSLC (2008) standard regarding families and communities (Collaborating with faculty and community members, responding to diverse community interests and needs, and mobilizing community resources) and the corresponding Chinese standard reveals one of these differences: school leaders were to "adjust to external contexts."

In Latin America, the adoption or adaptation of leadership frameworks and standards has varied (Flessa et al., 2018). Weinstein and Hernandez, 2016) studied eight Latin American school systems, seven countries (Argentina, Chile, Colombia, Ecuador, Mexico, Dominican Republic, and Peru) and one Brazilian sub-region (Ceará). Results revealed a wide range: systems with centrally developed leadership frameworks and standards in place (Chile, Colombia, and Ecuador) to systems with no leadership standards in place (Argentina, Ceará/Brazil). However, Brazil's recent adoption of learning standards for students (Rivas and Sanchez, 2020) may indicate that leadership standards are not far behind. In Chile, for example, The Framework for Good Principals and School Leadership (Ministerio de Educación de Chile, 2015) delineates a number of areas (including vision, goal setting, and monitoring of instruction) that guide principals' behaviors. The framework includes direction on how principals should work with families to "encourage and facilitate the involvement of families in the education of their children ... for which they provide information and generate concrete and systematic spaces to involve them, in order to generate a collaborative relationship" (translated from Spanish, Sisto, 2018, p. 149). Independent of the extent to which standards align with professional development for school leaders or leaders' actual behaviors, Chilean educational policy points to the priority placed on principals working collaboratively with families.

In 2015, the South African government formally adopted "The South African Standard for Principals" which provides guidance for school leaders in eight key areas, including a particular emphasis on the processes of teaching and learning (Moorosi, 2020). The sixth area, working with and for the community, advises principals to be cognizant of "the socio-economic, political and cultural characteristics of the wider school community" and further directs principals to "build and maintain partnerships between the school, the home and the wider community" (Department of Basic Education, South Africa, 2015, p. 21). However, within the context of highly racialized educational and community environments, Moorosi (2020) critiques the "colour-blind" language used throughout the policy.

Standards for school leaders continue to be created, borrowed, and/or adapted in non-Western countries around the world. In many cases, professional development for principals has yet to be offered and changes in practice has yet to be documented in research. Nevertheless, as Table 1 below illustrates, a clear emphasis on working *with* families and community partners in a reciprocal and equity-minded manner is evident in an examination of policy documents.

Table 1 A cross-country comparison of school leaders' professional standards related to family and community engagement.

Country	Author and date	Leadership standards	Standard related to family and community engagement
United States	National Policy Board of Educational Administration, 2015	Professional Standards for Educational Leaders (PSEL)	"Effective educational leaders engage families and community in meaningful, reciprocal, and mutually beneficial ways to promote each student's academic success and well-being" (PSEL, 2015).
United Kingdom	Department for Education, UK Government, 2020	National Standards for Headteachers	Headteachers must "forge constructive relationships beyond the school, working in partnership with parents, carers and the local community" (UK Government, 2020).
Ontario, Canada	Ontario Ministry of Education, 2013	The Ontario Leadership Framework, School Level Leadership Model	School leaders must "Build productive relationships with families and communities" (Ontario Ministry of Education, 2013) that include welcoming parents, viewing them as partners, building trust, and working with diverse families.
China	The Ministry of Education for the People's Republic of China, 2013	Professional Standards for Compulsory Education School Principals	The public relations standard encourages, "the capacity to negotiate with public relations, and to establish collaborations between the school, government, families, communities, and institutions" (Ministry of Education for the People's Republic of China, 2013).
Chile	Ministerio de Educación de Chile, 2015	The Framework for Good Principalship and School Leadership	States that principals should work with families to "encourage and facilitate the involvement of families in the education of their children ... for which they provide information and generate concrete and systematic spaces to involve them, in order to generate a collaborative relationship" (translated, Sisto, 2018, p. 149).
South Africa	Department of Basic Education, South Africa, 2015	The South African Standard for Principalship	The sixth area, working with and for the community, advises principals to be cognizant of "the socio-economic, political and cultural characteristics of the wider school community" and further directs principals to "build and maintain partnerships between the school, the home and the wider community" (Department of Basic Education, South Africa, 2015, p. 21).

Family engagement around the world: an international view

We know that school leaders play an important role for establishing school-family partnerships (Jung and Sheldon, 2020) and positioning family engagement "both as an outcome *and* a means for providing a quality education for students" (emphasis added, DeMatthews et al., 2016, p. 756). However, as noted earlier, we live in a challenging and changing world that shapes the everyday context of schools, families, and communities. Thus, "research in highly demanding contexts across the globe is needed to further develop theory and practical applications" in the field (DeMatthews et al., 2016, p. 755). Accordingly, in what follows, we discuss research conducted in highly demanding contexts. We also consider international contexts related to Indigenous education.

In the context of the United Kingdom, contemporary social challenges that shape school leaders' work include security/safety, poverty, inequality, chronic absenteeism, and high school dropout rates. In a study examining the dynamics between primary school leadership and parental engagement in the United Kingdom, Mleczko and Kington (2013) demonstrate "the importance of the school principal in facilitating opportunities for increased parental engagement that promoted social inclusion and cohesion between/among parents, volunteers, and professionals, particularly in the context of highly disadvantaged areas" (p. 143). The schools that were studied as part of this qualitative research were "characterized by a high presence of ethnic minority children and were located in a neighborhood of low social and economic status in the Midlands region of the United Kingdom" (p. 129). The findings from the research brings evidence "that the role of the school principal is crucial in the introduction, implementation and sustainability of solutions focused on parental involvement, as well as bringing benefits to the social cohesion of the local community" (p. 143). In their own words, the scholars noted:

... [A]s part of establishing a culture in schools that encourages parental involvement, it is important that the leadership vision for the school is clearly communicated, and responsive to the school and community context. Furthermore, this vision needs to be positive and optimistic in tone if members of staff are to feel that they have the opportunity to innovate and be part of a team that can achieve the goal of continuing to foster improved parental involvement (p. 143).

In other words, school leaders play a key role in mitigating distributive and cultural factors that shape school-family dynamics and promote social cohesion within ethnically diverse communities.

In Mexico, DeMatthews et al. (2016) offer a qualitative case study exploring the enactment of social justice leadership in a private elementary school located in the *colonia* of Ciudad Juarez, a highly demanding context in the US-Mexico border. As noted by the authors,

Colonias are unincorporated and unregulated settlement with substandard housing and living conditions that present numerous obstacles to student well-being and achievement, including (a) high proportions of adult illiteracy; (b) lack of access to quality public schools; (c) severe poverty; (d) domestic violence, gang/cartel violence, and the persistence of violent and nonviolent crime; (e) government malaise/corruption; and (f) a lack of community cohesion and solidarity

Bejerano (2002), Hernandez and Grineski (2012), Heyman and Campbell (2004), Hill (2003), p. 756.

The research describes how the school principal prioritized meaningful family engagement as part of addressing *out-of-school* factors that influenced the social and academic outcomes of students. For instance, to address issues related to violence, extortion, governmental oppression, corruption, and precarious housing and everyday living conditions, the school principal engaged with family members to increase safety and accessibility, provide expanded learning opportunities (e.g., adult education, extended day, after school programs), and cultivate critical leadership skills. While this study used a year-long data collection process, it is important to note that the principal, the school's founder, had been working with families and the community for over a decade. With this sustained focus, the principal's aim was to disrupt status quo thinking, address local problems, and support long-term community capacity development. In other words, the explicit intention was to (re)build trust and increase family engagement and community solidarity over time. In so doing, the principal worked with families in an inclusive and democratic manner that leveraged school resources and supported marginalized families.

In the Australian context, cultural and linguistic diversity, especially with regards to Aboriginal children and families, has inspired school leaders to move toward a two-way street approach to school-family partnerships in early childhood and elementary schools. A one-way street approach is one where schools focus on educating families as part of pre-decided school-based efforts and goals (Sisson et al., 2021). However, a more democratic two-way and parents/families, teachers/staff, and school leadership collaborate and learn together. To this extent, Sisson and colleague's multiple case study research explored how two schools in Australia engaged with Reggio Emilia education principles to reimagine school-family partnerships (p. 2). As a result of engaging with theory-grounded family engagement practices, school leaders and teachers enacted a more collaborative "two-way street" approach when working with families. This approach included co-designing school spaces and co-planning school-based programming and community-wide events that were informed by shared goals. Here it is also important to point out that school leaders *and* teachers collaborated in reframing family engagement efforts at both school communities. In other words, school leaders cannot do this work this work alone. Teachers, staff, families, and neighborhood residents are all important stakeholders in the process of moving toward a two-way street approach to school-family partnerships in education.

In recent years, there has been a growing recognition of the ways in which a long and grievous history of colonization in countries around the world continues to impact negatively the school experiences of Indigenous students and families (Battiste, 2017; Bishop, 2021; Smith et al., 2018). In particular, in countries such as Canada, Australia, French Indochina, and the United States, government officials removed Indigenous and part Indigenous children from their homes and families and placed them in residential schools where children faced inhumane conditions and abuse (Firpo and Jacobs, 2018). Bang et al. (2018) write "systems of education for Indigenous children and youth often remain sites of trauma, assault, and aims of Indigenous erasures" (pp. 1–2) and advise instead, family engagement should honor "Indigenous families' and communities' ways of knowing and being" and engage "Indigenous families and communities as dreamers, nation-builders, and future elders" (Bang et al., 2018, p. 2). In a similar vein, Garcia (2014) queries how re-framing parental involvement from an Indigenous perspective might "disrupt notions of treating parents as uninvolved or deficient, and begin to privilege Indigenous families as a source of strength and commitment to education from an Indigenous *and* western perspective?" (p. 61). Corn tassel and Hardbarger's (2019) work elucidates the importance of everyday actions *in* families and communities and *on* the land that forms the basis for education and decision-making from an Indigenous perspective. Thus, from an Indigenous perspective, parents and families play a central, not peripheral, role in the perpetuation of knowledge and land-based, not school-based, education is prioritized.

While most of the aforementioned research accounts for single and/or multiple case studies conducted at the school site level, a growing number of scholars are examining family engagement from a broader, yet place-based perspective that accounts for school-family-community dynamics within a district or in a geographic area ((Alameda-Lawson, 2016) Hopson, 2014). For instance, a qualitative thematic synthesis (Alameda-Lawson, 2014; Lawson et al., 2016) of school-family-community partnerships in three low-income, ethnically concentrated urban school communities in the United States (one in South Florida and two in Northern California) utilized a *collective parent engagement approach* (CPE). Social workers engaged with parents to design and develop school-based and/or school-linked programs and services that could support the strengths, needs, and challenges of children and families in the neighborhood community (p. 1085). The authors noted, "when implemented as an isolated or 'stand-alone' service strategy, CPE generally does not influence school outcomes. But when tied to a broader system of reform efforts,

CPE can help transform the social-institutional landscape of low-income urban school communities" (p. 1085). Thus, the findings "serve as an important reminder of the limitations of any single intervention to affect change, especially interventions that are not well integrated with the work of school leaders, teachers, social and neighborhood providers, funders, and policy makers (Gutierrez and Penuel, 2014)" (p. 1114). Accordingly, this body of literature supports the idea that family engagement is not a program or a service, but rather a set of leadership practices and mediating conditions in schools and families that form part of broader improvement goals or reform efforts (Mapp and Bergman, 2021; Leithwood, 2021, in press).

Comprehensive reform efforts: community schools as a promising strategy

An international review of the scholarship about leadership factors and family engagement points to existing and thriving practices that are important to recognize, support, and study further. Thus, we highlight the **community school model** as an international approach to education that is grounded school-family-community partnerships (Anderson-Butcher and Ashton, 2004; Anderson-Butcher et al., 2018; Dryfoos, 1994; Dryfoos et al., 2005; Galindo et al., 2017; Galindo and Sanders, 2019a,b (Sanders, 2006, 2016, 2018)). As noted by Jenkins and Duffy (2016), community school is an umbrella term that refers to "schools that adopt a broad and varying range of services to address the comprehensive needs of students, families, and communities (p. 2)." Accordingly, "each community school should be unique to serve the specific needs of the local population" (p. 2). Moreover, the "composition of services and support might also vary due to funding constraints, funding considerations, or other factors" (p. 2). However, a key component of the community school model is the use of external partnerships "to transform the school into a neighborhood hub for social services and integrated student supports" (p. 2).

Since approaches to school-community partnerships vary widely in scope, purpose, and requirements, Valli and colleagues (Stefanski et al., 2016; Valli, 2016; Valli et al., 2014) offer a helpful typology of school-community partnerships. This analytical tool can be used to better understand the similarities and differences between family and interagency collaboration, full-service schools, full-service community schools, and a community development model. That being said, most approaches share the purpose of responding to community needs as an equity strategy (i.e., addressing education inequality more systemically, Task Force on Next Generation Community Schools, 2021).

For example, Community schools in Saskatchewan, Canada (Salm et al., 2016); in Ghent, Belgium (Blaton and Van Avermaet, 2016), and in the northern territory of Australia (Kamara, 2017) share a comprehensive approach yet vary in response to particular contexts and community needs (FitzGerald and Quiñones, 2018a, p. 1). For this reason, the *Coalition for Community Schools* (2021) notes that a community school is often referred to as "the hub of its neighborhood; it is a place and space that unites families, educators, and community partners to promote equity and excellence for children and families; it is an approach that strengthens families and communities" (p. 1).

Although implementation of the community school model vary-in-context, scholar-practitioners recommend the adoption of *four core pillars* to increase fidelity within the "scaling up" process (Task Force on Next Generation Community Schools, 2021, p. 24). According to Maier, Daniel, and Oakes from The Learning Policy Institute (2017), four features characterizing community schools that effectively support conditions for teaching and learning include: (a) integrated student supports; (b) expanded learning time and opportunities; (c) active family and community engagement; and (d) collaborative leadership and practice. Furthermore, effective community schools "fund full-time community school coordinators/directors to ensure quality implementation and increase return on investment by leveraging civic engagement and community resources toward desired outcomes" (*Coalition for Community Schools*, 2021, p. 13). It is important to note that community school coordinators, in tandem with school principals and community partners, lead efforts to integrate family-centered services and to expand learning opportunities for students (Bloodworth and Horner, 2019; *Coalition for Community Schools*, 2021; Mayger and Hochbein, 2019; FitzGerald and Quiñones, 2018b; Sanders et al., 2019).

In so doing, the community school model accounts for a promising strategy that rejects deficit views of families and calls upon families and community partners to implement educational practices grounded in shared goals, civic engagement, and systemic efforts (Fehrer and Leos-Urbel, 2016; Green, 2018; Heers et al., 2016 (McWayne et al., 2021; Min et al., 2017)).

Conclusion

As we close this scholarly journey through the intersection of leadership and family factors, we re-emphasize the importance of school leaders who co-design models of systemic engagement with multiple stakeholders. Family engagement is not a program, but rather a core element of effective and equitable educational practices. Historical views accentuate the evolution of parental involvement in a Western context and lead to broader discussions about the role and responsibilities of school leaders when working with families to support educational outcomes. Standards for school leadership signal the importance of families and communities in a local and global context, and the community school model illustrates a comprehensive place-based reform strategy that centers asset-based family engagement.

Many educators take the view that working together with others is a major means of achieving improvements in schools. The danger is that this belief can distract attention from the complexities involved in achieving effective forms of collaboration. There is a related risk that policy makers, seeing collaboration as the silver bullet of educational reform, might decide to mandate it as a means of achieving success. In so doing, they may overlook how other policies make this difficult.

With these concerns in mind, in this paper I reflect on many years of working with colleagues on a programme of development and research projects that have been based around collaborative ways of working (see summaries in: Ainscow, 2015, 2020). In so doing, I point to the many possibilities that this approach offers whilst, at the same time, examining the barriers that can obstruct progress. This analysis leads me to identify the conditions that are needed in order to make collaboration work, focusing in particular on what I see as the major challenge facing education systems around the world, that of achieving inclusion and equity. In this context, my focus is on factors at all levels of an education system, from the office of the minister, to the district level and through to what teachers do in their classrooms.

A global agenda

Since 1990, international impetus regarding inclusion in schools has been provided by the United Nation's Education for All (EFA) movement, which has worked to make basic education available to all learners. However, despite the progress that has been made over that period, recent UNESCO data show that progress has slowed in recent years, leaving some 258 million children, adolescents and youth still not in school, and more than 617 million children and adolescents not achieving minimum proficiency levels in reading and mathematics (UIS, 2019). It is also important to recognize that inequality in education has increased, with the poorest and most disadvantaged shouldering the heaviest burden.

Whilst this situation is most acute in the developing world, there are similar concerns in many wealthier countries, as noted by the OECD (2012), which reports that across its member countries, almost one of five students does not reach a basic minimum level of skills to function in today's societies. It is also noted that students from low socio-economic background are twice as likely to be low performers, implying that personal or social circumstances are obstacles to achieving their educational potential.

In responding to these challenges there is growing interest internationally in the use of strategies that place an emphasis on the power of market forces (Lubienski, 2003). In particular, some national education policies are encouraging schools to become autonomous; for example, in parts of Australia, the independent public schools; the academies in England; charter schools in the USA; the voucher reforms in Chile; and free schools in Sweden. Alongside this emphasis on school autonomy is a focus on parental choice. This usually takes place within education systems where high-stakes testing systems are intended to inform decision making, whilst at the same time driving improvement efforts (Au, 2009). In addition, narrowly defined measures of effectiveness are used for purposes of accountability (Schildkamp et al., 2012).

This global policy trend is a matter of considerable debate and there are varied views as to the extent to which it is leading to the desired outcomes. In particular, there is a concern that the development of education systems based on autonomy, coupled with high-stakes accountability and increased competition between schools, will further disadvantage learners from low income and minority families (Salokangas and Ainscow, 2017).

Whilst such developments have the potential to open up possibilities to inject new energy into the improvement of education systems, there is growing evidence from a range of countries that they are leading to increased segregation that further disadvantage learners from economically poorer backgrounds (Pickett and Vanderbloemen, 2015). So, for example, talking about the development of charter schools in the USA, Kahlenberg and Potter (2014) suggest they have led to increased segregation in school systems across the country and similar patterns are reported from Sweden (Wiborg, 2010). In relation to Chile, Zancajo (2019) explains how the context of a competitive environment has led to processes of exclusion that affect students from low socioeconomic backgrounds, foster school segregation and increase educational inequalities. Meanwhile, in New Zealand, a recent government concluded that a key reason for the country's poor equity and achievement outcomes is that schools have predominantly operated as autonomous, self-managing entities, loosely connected to each other, and with a distant relationship with the center (Ministry of Education, 2019). This autonomy, it is argued, has left schools to operate largely on their own and without sufficient support.

Meanwhile, in my own country, England, we have reported how the creation of academy schools has reduced the level of funding that is available elsewhere throughout the education system and, in particular, diverted resources away from local authorities and the schools that remain within their control (Ainscow et al., 2016). Moreover, the manipulation of admissions suggests that these initiatives are contributing more directly to social segregation by effectively selecting "easy-to-teach students" into favorably funded schools. It seems, that, as with other reforms badged as movements towards greater school autonomy, any gain in this direction comes at a price.

A different way

There are, however, countries that have made progress by adopting a very different approach, one that involves an emphasis on collaboration and networking in order to combine quality with equity (OECD, 2012). In these contexts, the vast majority of students have the opportunity to attain high level skills, regardless of their own personal and socio-economic circumstances.

Encouragement for this view is provided by the "Report Card" prepared for Unicef by the Innocenti Center (2018). Focusing on high and middle-income countries, it concludes:

Tackling educational inequality does not mean sacrificing high standards. Countries with higher average achievement tend to have lower levels of inequality... Bringing the worst performing students up does not mean pulling the best-performing students down (p. 3).

Warning against the temptation to copy what more successful countries do well, the authors of the report argue that, whilst there are undoubted lessons that can be learned from these countries, they must be replicated with care. There are, it argues, many sources of inequality in education related to political, economic, social, cultural and institutional contexts, and these vary across countries.

In thinking about what is needed to use collaboration as a strategy for promoting equity within education system, there is also a need to rethink the way systems are managed. In particular, we need to reflect on the recommendations of the OECD in regard to developments in Scotland:

In our view there is need now for a bold approach that moves beyond system management... new dynamic and energy to be generated nearer the learning level... We call for a strengthened "middle" operating through networks... within and across local authorities... to create coherent and cohesive cultures of system-wide improvement.

OECD (2015, p. 15).

This suggests that some form of local coordination is needed in order to encourage collaborative activity.

Bringing the international policy context up to date, the year 2016 was particularly significant. It saw the publication of the Education 2030 Framework for Action (UNESCO, 2017). This emphasizes inclusion and equity as laying the foundations for quality education. It also stresses the need to address all forms of exclusion and marginalization, disparities and inequalities in access, participation, and learning processes and outcomes.

Taking account of this international policy agenda, in what follows I argue that effective change requires processes of social learning and knowledge creation within settings that stretch from multiple classrooms to the committee structures of senior policy makers. In particular, I reflect on evidence from a series of studies, carried out with my colleagues over the last three decades in a variety of national contexts, in order to consider how such approaches can be operationalized.

Inquiry-based developments

The development of the approach I am recommending began with the "Improving the Quality of Education for All" (IQEA) project in the early 1990s. Initially this involved a small group of researchers at the University of Cambridge working with schools in and around London (Ainscow and Hopkins, 1992). Subsequently, IQEA led to developments in other parts of the world (see Ainscow,

1999; Clarke et al., 2006; Hopkins, 2007; Hopkins et al., 1994; Hopkins et al., 1996; West and Ainscow, 2010 for more detailed accounts of some of these projects). All of these activities involved teams of researchers working in partnership with networks of schools to identify ways in which the learning of all members of a school community—students, parents and staff—could be enhanced.

Work with schools in the IQEA projects was based upon a contract that attempted to define the parameters for our involvement, and the obligations those involved owed to one another. It emphasized that all staff be consulted; that an in-school team of coordinators be appointed to carry the work forward; that a critical mass of staff were to be actively involved; and that sufficient time would be made available for necessary classroom and staff development activities. Meanwhile, we committed ourselves to supporting the school's developments, usually in the first place for 1 year. Often the arrangement continued, however, and, in some instances, we were involved for periods as long as 7 years. We provided training for the school coordinators, made regular school visits and contributed to school-based staff development activities. In addition, we attempted to work with the schools in recording and analyzing their experiences in a way that also provided data relevant to our own on-going research agendas.

As a result of such engagements with schools involved in the IQEA project, we evolved a style of collaboration that was to influence later initiatives, which we referred to as “working with, rather than working on” (Ainscow and Southworth, 1996). This phrase attempted to sum up an approach that deliberately allowed each project school considerable autonomy to determine its own priorities for development and, indeed, its methods for achieving these priorities. In attempting to work in this way, we found ourselves confronted with staggering complexity, and by a bewildering array of policy and strategy options. It was our belief that only through a regular engagement with these complexities could a greater understanding of school change be achieved.

These ideas were taken forward and developed through a series of further studies:

- *Understanding and Developing Inclusive Practices in Schools*. This collaborative action research study occurred between 2000 and 2004, and involved a network of 25 urban schools in three English local education authorities and three partner universities. Within the network schools, we saw how the use of evidence to study teaching can help to foster the development of more inclusive forms of teaching (see: Ainscow et al., 2004, 2006a; Dyson et al., 2003; Howes et al., 2004, 2005).
- *The Stockborough Equity Research Network*. Between 2006 and 2011 we had a chance to explore these ideas in more detail through our involvement in another network of schools England (see Ainscow et al., 2012a,b). This initiative was located in a local authority, which we called “Stockborough”, characterized by socio-economic disadvantage, and social and ethnic segregation. It involved staff inquiry groups in participating schools, usually consisting of five or six members representing different perspectives within their school communities.
- *Ethical Leadership: A collaborative investigation of equity-driven evidence-based school reform*. This study involved a research network of schools, spread across the geographically spread State of Queensland, Australia, and a team of eight university researchers who, together, explored how ethical leadership could promote ways of interpreting and using various forms of evidence to promote learning and equity (see: Harris et al., 2017, 2019; Spina et al., 2019).
- *Inclusive Inquiry*. Carried out between 2012 and 2020, this programme of research focused more specifically on how students can contribute to the development of inclusive teaching and learning. It involved the development of a strategy in which children becoming researchers who learn how to use research techniques to gather the views of their classmates, as well as observing lessons (see: Ainscow and Messiou, 2017; Messiou et al., 2016; Messiou and Ainscow, 2015, 2020).

All of these studies involved teams of university researchers in supporting, recording and analyzing collaborative action research as it occurred in project schools. As a result, we came to define this as a process of knowledge-generation that occurs when researcher and practitioner knowledge meet in particular sites and is aimed at producing new knowledge about ways in which broad values might better be realized in future practice.

This approach has significant implications for the relationship between researchers and practitioners. It requires new forms of partnership, in the way that is outlined helpfully by Hiebert et al. (2002) who suggest that fruitful forms of collaboration require a reorientation of values and goals amongst both groups. So, they argue, teachers need to move away from the dominant view that teaching is a “personal and private activity”. Rather, teachers have to adopt the “more risky view” that it is an activity that can be continuously improved, provided it is made public and examined openly. At the same time, they argue that researchers must stop undervaluing the knowledge teachers acquire in their own classrooms. In this way researchers are able to recognize the potential of personal knowledge as it becomes transformed into professional knowledge.

A family of approaches

These studies adopted different terms to describe their efforts, such as collaborative inquiry, practitioner action research, action learning and lesson study. Recently Yurkofsky (2020) have labeled approaches such as these collectively as “continuous improvement” methods, noting that they share four characteristics:

1. Grounding improvement efforts in local problems or needs;
2. Empowering practitioners to take an active role in research and improvement;
3. Engaging in iteration, which involves a cyclical process of action, assessment, reflection, and adjustment; and
4. Striving to encourage change across schools and systems, not just individual classrooms.

They can be seen as being part of a “family” of approaches within the overall tradition of action research (Reason and Bradbury, 2001) that developed out of the action research tradition of Kurt Lewin (1946) and the work of many other academics (e.g., Cochran-Smith and Lytle, 2009; Elliot, 1991; Kemmis and McTaggart, 1988; Schön, 1983; Stenhouse, 1975). They emphasize an engagement in inquiry to inform and improve practice, and the intentional combining of knowing and doing for achieving positive social change (Kemmis, 2010).

Since the focus of the inquiry is usually defined by the engagement of the participants, careful consideration is required in determining who is included, and how and who will speak for whom, and who sets the research agenda. Therefore, negotiating power issues and the relationships between collaborating practitioners, stakeholders and academics “requires ethical probity where each party recognizes, understands and respects mutual responsibilities” (Campbell and Groundwater-Smith, 2007, p. 2).

The preoccupation with equity means that it also requires a particular concern to giving voice to those who may be powerless or unheard in the decision-making processes (Groundwater-Smith, 2011). Moreover, actively engaging participants in inquiry “problematizes the question of who is researcher and who is researched, raising issues around anonymity, the ‘ownership’ of findings and dissemination” (Locke et al., 2013, p. 107).

Related considerations concern decision-making around how outcomes will be evaluated in order to determine whether the inquiry processes have led to positive change. Questions to be considered include:

- What forms of evidence will be used to determine the outcomes for those who have participated in the process and those who are the intended beneficiaries of the change efforts that were the focus of the project?
- How far did processes improve the social and professional practices in the contexts in which they were conducted?
- How will the outcomes from the inquiry be used?

Participatory and collaborative inquiry processes, although not set on achieving consensus, do provide opportunities for negotiation of multiple perspectives around shared agendas, rather than producing evidence from a single viewpoint or source. A helpful strategy in this respect is what Wasser and Bresler (1996) refer to as “group interpretive processes” as a means of analyzing and interpreting evidence. This involves an engagement with the different perspectives of practitioners, students and university researchers in ways that are intended to encourage critical reflection, collaborative learning and mutual critique. In these contexts, the varied theoretical perspectives of members of the research teams provide a valuable means of questioning taken-for-granted assumptions and helping practitioners to reconsider neglected possibilities for moving practice forward.

The issue of trustworthiness is a particular challenge to collaborative research of this sort, which involves such a high degree of participation among stakeholders. Commenting on this issue, Schon (1991) argues that without a serious effort to make clear what is meant by rigor, participatory research “becomes an open sesame to woolly-headedness, a never-never land where anything goes” (p. 10). He goes on to suggest that appropriate rigor in the study of practice should focus on validity (e.g., how do we know what we claim to know?) and utility (e.g., how useful is the research to practitioners?).

With this in mind, the studies I have described made use of three forms of triangulation, supporting observations and reports from a number of viewpoints. These involved comparing and contrasting evidence about the same actions and activities from different people (e.g., teachers, support staff and students); scrutinizing events from different angles by making use of a variety of methods for collecting information; and using “outsiders” as observers.

Influenced by the ideas of Karl Popper, Schon (1991) argues that the fundamental test for validity in participatory enquiry is through “competitive resistance to refutation”. This involves juxtaposing alternate plausible accounts of the phenomenon in question. Schon notes: “In the absence of an alternate hypothesis, one is likely to be overwhelmed by the obviousness of what one already knows” (p. 348).

Guided by this advice, members of our research teams usually discussed with their practitioner partners, and with one another, written accounts of the work carried out in the schools, including alternative explanations as to what lessons could be drawn from these experiences. In this way, the aim was to draw conclusions that were both valid and relevant.

A framework for analysis

The studies summarized so far were all guided by the principle of equity, which, following the lead of OECD (2012), is taken to involve notions of inclusion and fairness. Working with schools in different contexts over many years, those involved in the research became increasingly aware of the complexities this involves. This led to the development of an overall framework to guide the development of the collaborative action research, referred to as an “ecology of equity” (Ainscow et al, 2012a). This formulation involves three interlinked areas within which equity issues arise:

- *Within-schools*. These are issues that arise from school and teacher practices.
- *Between-schools*. These are issues that arise from the characteristics of local school systems.
- *Beyond-schools*. This far-reaching arena includes: the wider policy context within which schools operate; the family processes and resources which shape how children learn and develop; the interests and understandings of the professionals working in schools; and the demographics, economics, cultures and histories of the areas served by schools.

Drawing on the findings of the studies referred to above, in what follows possibilities for linking within-school, between-school and beyond-schools factors in order to develop effective collaborative improvement approaches are explored.

Within-school factors. My colleagues and I have argued that “schools know more than they use” (Ainscow et al., 2012a). In other words, schools tend to have overlooked expertise that can be mobilized to address the challenge of equity. This suggests that the starting point for strengthening the work of a school is with the sharing of existing practices through collaboration amongst staff, leading to experimentation with new practices that will reach out to all students. This approach draws on the work of the many scholars who have explored processes of collaborative inquiry as a strategy for professional learning and school improvement.

Much of what teachers do during the intensive encounters that occur is carried out at an automatic, intuitive level. Furthermore, there is little time to stop and think. This is why having the opportunity to see colleagues at work is so crucial to the success of attempts to develop practice. It is through shared experiences that colleagues can help one another to articulate what they currently do and define what they might like to do (Hiebert et al., 2002). It is also the means whereby space is created within which taken-for-granted assumptions about particular groups of learners and what they might achieve can be subjected to mutual critique, a factor that is crucial to the promotion of inclusive practices.

At the heart of the processes in schools where changes in practice do occur is the development of a common language with which colleagues can talk to one another and, indeed, to themselves, about detailed aspects of their practice (Huberman, 1993). Without such a language, teachers find it very difficult to experiment with new possibilities (Ainscow, 1999).

In a recent article, Lefstein et al. (2020) point to the importance of the conversations embedded in teachers’ day-to-day work, through which they learn from one another what it means to be a teacher and how to perform their duties. The authors explain how professional knowledge and skills, much of which are implicit, are learned on the job, through participation in work practices and informal interactions with colleagues. This means that professional knowledge is intimately related to the practices through which it is constructed and to which it is applied. Given the situated nature of knowledge, ideas constructed with colleagues at school are more likely to be used within a school, whereas ideas constructed within professional development workshops are only likely to be applied in the social practice of participating in such events.

An engagement with evidence of various kinds to study teaching within a school can help in generating school-based professional learning (Ainscow et al., 2004). This, in turn, can help to foster the development of practices that are more effective in engaging hard to reach learners. Specifically, it can create space for rethinking by interrupting existing discourses. The starting point for such processes is often with a consideration of statistical evidence regarding student progress. However, the need to dig deeper into factors that influence progress usually requires an engagement with qualitative forms of evidence. Particularly powerful techniques in this respect involve the use of mutual lesson observation, sometimes through video recordings, and evidence collected from students about teaching and learning arrangements within a school.

Under certain conditions such approaches provide “interruptions” that help to make the familiar unfamiliar in ways that stimulate self-questioning, creativity and action. In so doing they can sometimes lead to a reframing of perceived problems that, in turn, draws the teacher’s attention to overlooked possibilities for addressing barriers to participation and learning. In this way, differences amongst students, staff and schools can become a catalyst for improvement.

Here, the concern with the principle of equity means that there also has to be focus on the thinking that is *behind* actions and the impacts of such thinking on practices. In particular, there has to be a concern with the attitudes and assumptions that influence what teachers do, some of which may be unconscious (Sadker et al., 2009), and how these can be modified through dialogs with others, especially with learners themselves. All of this points to the importance of forms of leadership that encourages colleagues to challenge one another’s assumptions about particular students (Riehl, 2000).

Between-school factors. The approach outlined so far is based on the idea of those within schools collecting and engaging with various forms of evidence in order to stimulate moves to create more inclusive practices. The studies I have summarized provide encouraging evidence of the potential of this approach. However, they have also thrown light on the difficulties in putting such thinking into practice, particularly within policy contexts that put pressure on schools to compete. This points to some of the limitations of within-school strategies, suggesting that these should be complemented with efforts to encourage greater cooperation between schools, and between schools and their wider communities.

The projects have generated considerable evidence that school-to-school collaboration can strengthen improvement processes by adding to the range of expertise made available (see: Ainscow, 2010, 2012, 2015; Ainscow and Howes, 2007; Ainscow and West, 2006; Ainscow et al., 2004, 2006b; Muijs et al., 2010, 2011). Together with the work of others (e.g., Chapman and Hadfield, 2010; Fielding et al., 2005; Hill, 2008), these studies indicate that collaboration between schools has an enormous potential for fostering the capacity of education systems to respond to learner diversity. More specifically, they show how such partnerships can sometimes help to reduce the polarization of schools within an education system, to the particular benefit of those students who seem marginalized at the edges of the system, and whose performance and attitudes cause concern.

There is also evidence that when schools seek to develop more collaborative ways of working this can have an impact on how teachers perceive themselves and their work (Muijs et al., 2011). Specifically, comparisons of practices in different schools can lead teachers to view underachieving students in a new light. In this way, learners who cannot easily be educated within a school’s established routines come to be seen less as “having problems” but as challenging teachers to re-examine their practices in order to make them more responsive and flexible.

It is important to realize, however, that developing partnerships between schools is not a straightforward process. Too often they can lead to meetings without any significant action. For example, in the networks referred to earlier, schools were encouraged to visit one another in order to generate evidence regarding their shared focus on developing more inclusive practices. However, these visits were not always successful. This seemed to be particularly so when the host teachers interpreted the visits solely as opportunities for the visitors to learn. On these occasions, the hosts positioned themselves as teachers rather than learners. Typically, the visit then

consisted of a demonstration of various teaching strategies that had been judged to be successful, usually followed by a short question and answer session. On these occasions, those receiving the visit merely rehearsed what they already knew and responded to questions beyond the procedural as if they were challenges, rather than openings for debate. On the other hand, successful visits were usually characterized by a sense of mutual learning amongst hosts and visitors. It was noticeable, too, that the focus for these visits often took some time to identify and clarify. Indeed, the preliminary negotiations that took place were in themselves a key aspect of the process.

Further convincing evidence of the power of schools working together comes from the City Challenge programmes in London and Greater Manchester. The success of these initiatives has been widely reported, leading to extensive debates as to what were the key factors that led to their impact (e.g., [Barrs et al., 2014](#); [Claeys et al., 2014](#); [Greaves et al., 2014](#); [Hutchings et al., 2012](#); [Kidson and Norris, 2014](#)).

An important feature of City Challenge was the emphasis placed on contextual analysis as the starting point for developments. This led to the conclusion that plenty of good practice existed across the schools in the two city regions. Consequently, it was decided that collaboration and networking would be the key strategies for strengthening the overall capacity of the system to reach out to vulnerable groups of learners. More specifically this involved a series of inter-connected activities for “moving knowledge around” ([Ainscow, 2015](#)). Once again, an engagement with evidence proved to be important in making this happen.

The powerful impact of the collaborative strategies developed in City Challenge points to ways in which improvement processes used within individual schools can be deepened and, therefore, strengthened. This involves an emphasis on mutual critique, within schools and between schools, based on an engagement with shared data. This, in turn, requires strong collective commitment from senior school staff and a willingness to share responsibility for system reform.

Beyond-school factors. Research suggests that the development of education systems that are effective for all children will only happen when what happens outside as well as inside a school changes ([Kerr et al., 2014](#)). Indeed, there is encouraging evidence of what can happen when what schools do is aligned in a coherent strategy with the efforts of other community players—families, employers, community groups, universities and public services. This does not necessarily mean schools doing more, but it does imply partnerships beyond the school, where partners multiply the impacts of each other’s efforts. However, experience suggests that the success of such partnerships is dependent upon a common understanding of what they are trying to achieve and, once again, an engagement with various forms of evidence to stimulate collective effort.

This approach draws on the principles underpinning the highly acclaimed Harlem Children’s Zone in the USA ([Whitehurst and Croft, 2010](#)). These involve efforts to improve outcomes for children and young people in areas of disadvantage through an approach that they characterize as being “doubly holistic”. That is to say, they seek to develop coordinated efforts to tackle the factors that disadvantage children and enhance the factors which support them, across all aspects of their lives, and across their life spans, from conception through to adulthood. [Dobbie and Fryer \(2009\)](#) describe the Children’s Zone as “arguably the most ambitious social experiment to alleviate poverty of our time” (p. 1).

Another American initiative, StriveTogether, acts as a central backbone organization for sites using similar ideas across the country that are locally tailored ([Grossman et al., 2014](#)). These initiatives are guided by indicators that span young people’s lives “from cradle to career”, with progress determined using data at all stages. The challenges involved in applying this thinking have been explored in the Children’s Neighborhoods Scotland initiative ([Chapman and Ainscow, 2021](#)).
